Summary

A composite analysis is required by U.S. Department of Energy (DOE) Order 435.1 to ensure public safety through the management of active and planned low-level radioactive waste disposal facilities associated with the Hanford Site. The original composite analysis in 1998 must be revised and submitted to DOE Headquarters in 2004 because of revisions to waste site information in the 100, 200, and 300 Areas; updated performance assessments and environmental impact statements; changes in inventory estimates for key sites and constituents; and a change in the definition of offsite receptors.

Beginning in fiscal year 2003, the DOE Richland Operations Office initiated activities, including the development of data packages, to support the 2004 Composite Analysis. The river data package provides calculations of flow and transport in the Columbia River system. The module is based on the legacy code for the Modular Aquatic Simulation System II (MASS2), which is a two-dimensional, depth-averaged model that provides the capability to simulate the lateral (bank-to-bank) variation of flow and contaminants. It simulates river hydrodynamics (water velocities and surface elevations), sediment transport, contaminant transport, biotic transport, and sediment-contaminant interaction, including both suspended sediments and bed sediments. MASS2 applies the general finite-volume principles to a multi-block curvilinear computational grid. Momentum and conservation of mass are coupled using a variation of the Patankar (1980) SIMPLE algorithm.

This document presents the data assembled to run the river module components for the section of the Columbia River from Vernita Bridge to the confluence with the Yakima River. MASS2 requires data on the river flow rate, downstream water surface elevation, groundwater influx, channel bathymetry, and the bed and suspended sediment properties. Stochastic variability for some input parameters such as partition coefficient (k_d) values and radionuclide concentrations is generated by the Environmental Stochastic Preprocessor (Eslinger et al. 2002). River flow is randomized on a yearly basis. At this time, the conceptual model does not incorporate extreme flooding (for example, 50 to 100 years) or dam removal scenarios.

Flow data are adequate to the current task of running at a monthly time step. Daily and hourly flow data are available if the time step is reduced in the future. A very good bathymetric grid has been developed that provides increased resolution where necessary. Sediment data are the least available, but there is little evidence demonstrating an immediate need for additional resolution on this model component. Partition coefficient values have been broadly defined with carefully defined distributions based on the best available data and stochastically incorporated into the model. Groundwater inputs are defined by the groundwater model results. Substantial data on radionuclide background levels and river inputs exist, and additional information is continually becoming available through programs such as the Hanford Environmental Information System and Hanford Site Environmental Surveillance.

1.0 Introduction

A composite analysis is required by U.S. Department of Energy (DOE) Order 435.1 to ensure public safety through the management of active and planned low-level waste disposal facilities associated with the Hanford Site (DOE M 435.1-1). The original composite analysis detailed in Kincaid et al. (1998) must be revised and submitted to DOE Headquarters because of revisions to waste site information in the 100, 200, and 300 Areas; updated performance assessments and environmental impact statements (EIS); changes in inventory estimates for key sites and constituents; and a change in the definition of offsite receptors.

Kincaid et al. (2004) describes the technical scope of the 2004 Composite Analysis for the Hanford Site and the approach to perform this analysis. It will be a site-wide analysis, considering final remedial action for the Columbia River corridor and the Central Plateau, and will be a companion site-wide assessment to waste-specific and site-specific assessments. The 2004 Composite Analysis also will provide supporting information on a regional or site-wide basis for use in important Hanford assessments and decisions such as the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) 5-year review in 2005, tank closure decisions, decisions on final groundwater remedies for the 200 Areas, decisions of final groundwater remedies for the 100 Areas, and the Columbia River corridor final record of decision.

Beginning in fiscal year (FY) 2003, the DOE Richland Operations Office (DOE-RL) initiated activities, including the development of data packages, to support the 2004 Composite Analysis. This report describes the data compiled in FY 2003 to support Columbia River modeling for the 2004 Composite Analysis. This work was conducted as part of the Characterization of Systems Task of the Groundwater Remediation Project (formerly the Groundwater Protection Project) managed by Fluor Hanford, Inc., Richland, Washington.

The purpose of this data package is to summarize the underlying data used as input for numerical simulation as part of the 2004 Composite Analysis and to provide the input parameters needed for the simulations. The general approach for this work was to extract data and interpreted information from existing documents and databases. Every attempt was made to provide traceability back to the original source of the data or interpretations.

2.0 Background

The long-term impact of the Hanford Site on ecological and human health is of interest to environmental managers, engineers, and scientists responsible for the cleanup, as well as the public. The Systems Assessment Capability (SAC) is a system of linked modeling tools and data intended to provide a way to evaluate these impacts. Details of the SAC models and the initial assessments are presented in Kincaid et al. (2000) and background information on the development of SAC is presented in Bryce et al. (2002),

which can be found at http://www.hanford.gov/docs/gpp/modeling/pnnl14027/river.pdf. SAC primarily consists of contaminant inventory estimates and models of contaminant release; vadose zone, groundwater, river, and shoreline models; and impact or risk assessment tools.

The River Flow and Transport Module provides the capability to calculate flow and transport in the Columbia River system. The module is based on the Modular Aquatic Simulation System in Two Dimensions (MASS2) is a two-dimensional (2D), depth-averaged hydrodynamics and transport model. The theoretical basis and use of MASS2 are presented in Perkins and Richmond (2004a) and Perkins and Richmond (2004b), respectively. The model simulates time varying distributions of depth-averaged velocities, water surface elevations, and water quality constituents. MASS2 uses a structured, multi-block, boundary-fitted, curvilinear computational mesh, which allows the simulation of very complex riverine or estuarine networks. The blocks may be of varying resolution, which allows high resolution to be used only where needed. MASS2 can simulate a wide variety of hydrodynamic conditions, including supercritical flow and hydraulic jumps. It can also simulate a wide variety of water quality conditions, including sediment, conservative or decaying contaminants, sediment-sorbed contaminants, water temperature, and total dissolved gas. Any number of these constituents may be simulated simultaneously. In addition, transport simulations may be performed using pre-calculated hydrodynamic conditions, allowing long-term transport simulations unencumbered by the more intensive hydrodynamic calculations, or repeated transport simulations without re-simulating hydrodynamics.

For the composite analysis, MASS2 is used to simulate river flows and contaminant transport through the Hanford Reach of the Columbia River. MASS2 uses groundwater and vadose zone inputs from other models in the Composite Analysis, and its output is used by the modules for impact assessment. This document presents the data assembled to run the river module for the section of the Columbia River from Vernita Bridge to the confluence with the Yakima River. The Environmental Stochastic Preprocessor (ESP) generates stochastic variability for some input parameters for many of the SAC modules (Eslinger et al. 2002). For the River Flow and Transport Module, ESP provides inputs such as the partition coefficient (k_d) values and radionuclide concentrations. River flow is randomized on a yearly basis. At this time, the conceptual model does not incorporate scenarios for extreme flooding (50 to 100 years) or dam removal.

3.0 Data Gathering Methods and Data Limitations

MASS2 requires data on the river flow rate, downstream water surface elevation, groundwater influx, channel bathymetry, and the bed and suspended sediment properties. In the subsections below, the data requirements, data sources, model inputs, and data limitations are discussed for each required component for the River Flow and Transport Module.

3.1 Bathymetry and the Computational Grid

River bathymetry describes the shape of the channel. Multiple data sources were integrated into a single bathymetric surface, then the bathymetric surface was used in the creation of the computational grid. The computational grid is the representation of the channel shape that is input into MASS2. Two distinct types of data are required for the creation of the computational grid: shoreline data defining the lateral extent of the river and bathymetric data to represent the shape of the river bottom.

3.1.1 Requirements

Accurate representation of the channel bathymetry is vital to realistically simulate the river depth and velocity characteristics. However, a coarse computational grid is necessary to maximize processing speed and ensure that the long time periods required by the composite analysis can be simulated in reasonable amounts of time. Therefore, the river channel features must be represented using as coarse of a grid as possible. To achieve this, a computational grid with variable grid cell densities was developed. The composite analysis computational grid has double the resolution in the cross-stream direction for complex regions of interest. These complex regions are represented by smaller grid cells while the less complex river segments are represented by larger, coarser grid cells (see Section 3.1.3).

3.1.2 Data Gathering

River bathymetry was based on data obtained in 1998 by the U.S. Geological Survey Biological Resource Division in Cook, Washington (Tiffan et al. 2002). A scanning hydrographic operational LiDAR survey (SHOALS) light detection and ranging (LIDAR) system (Irish et al. 2000) was used to measure bottom elevations in near shore and shallow areas. These point data and data from cross section surveys were used to create a continuous, three-dimensional bathymetric surface of the study area in ArcInfo (Figures 1 through 3).

The computational grid for the river simulations was based on this bathymetric surface and shorelines that included the large islands in the Hanford Reach. The shorelines were based on flows of 80 kcfs and digitized from aerial photos. The ArcInfo bathymetric surface was used to determine the bed elevation at each point in the computational grid. Recent MASS2 code enhancements allow grids with grid density changes at matched boundaries to be used. These enhancements allow the increased resolution around the islands, where it is needed, while reducing the computational time relative to having the higher resolution in all areas of the river. The new grid contains 58 blocks with a total of 2,708 cells.

3.1.3 Proposed Input Parameters

The computational grid, created in Gridgen, had 7 cells across in areas without islands, 14 cells across in areas with islands (Figure 4), and a total of 2,708 cells partitioned into 58 blocks. The grid extended from the Yakima River confluence (Columbia River mile [RM] 335) upstream to RM 389 near Vernita Bridge.

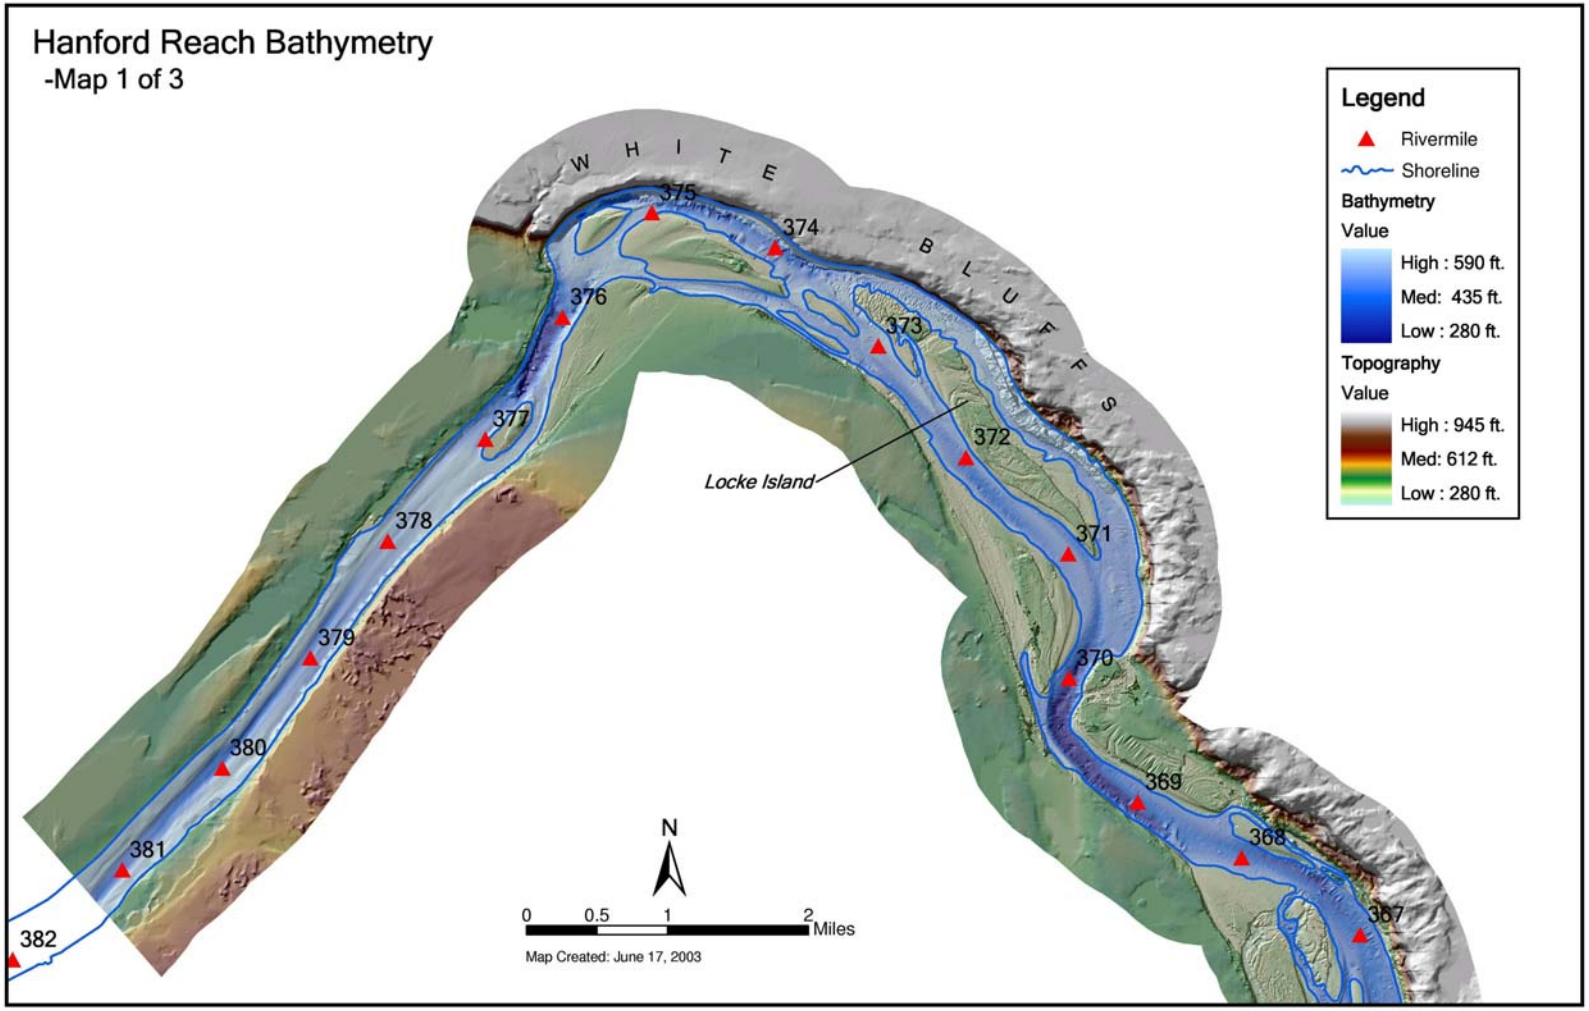

Figure 1. Updated Bathymetry, River Mile 368 to 381

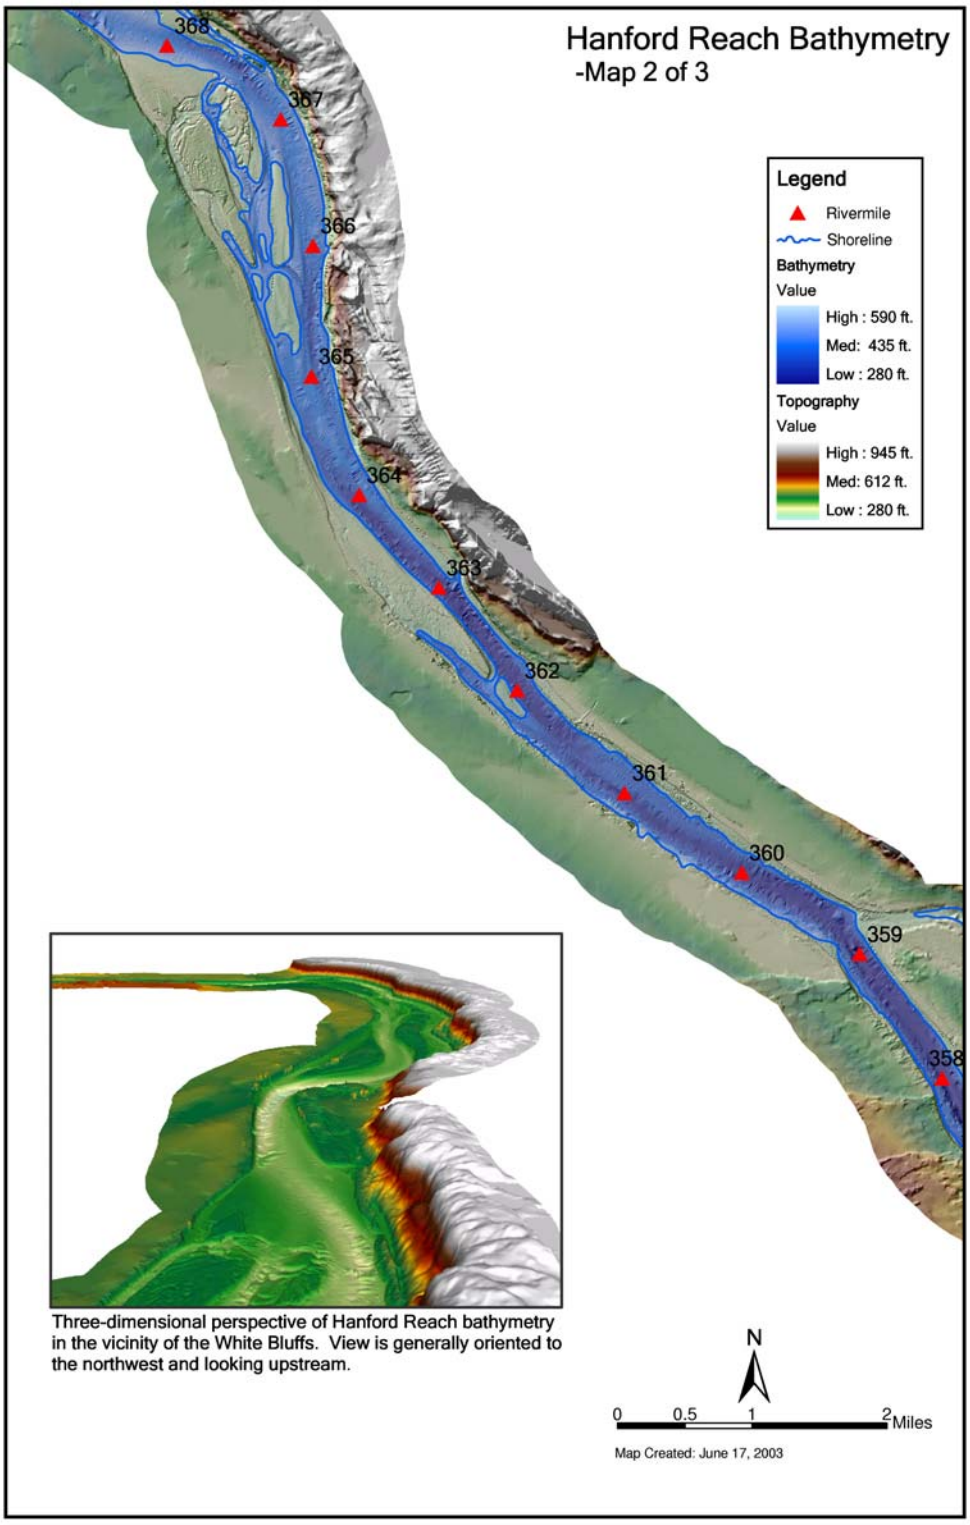

Figure 2. Updated Bathymetry, River Mile 359 to 367

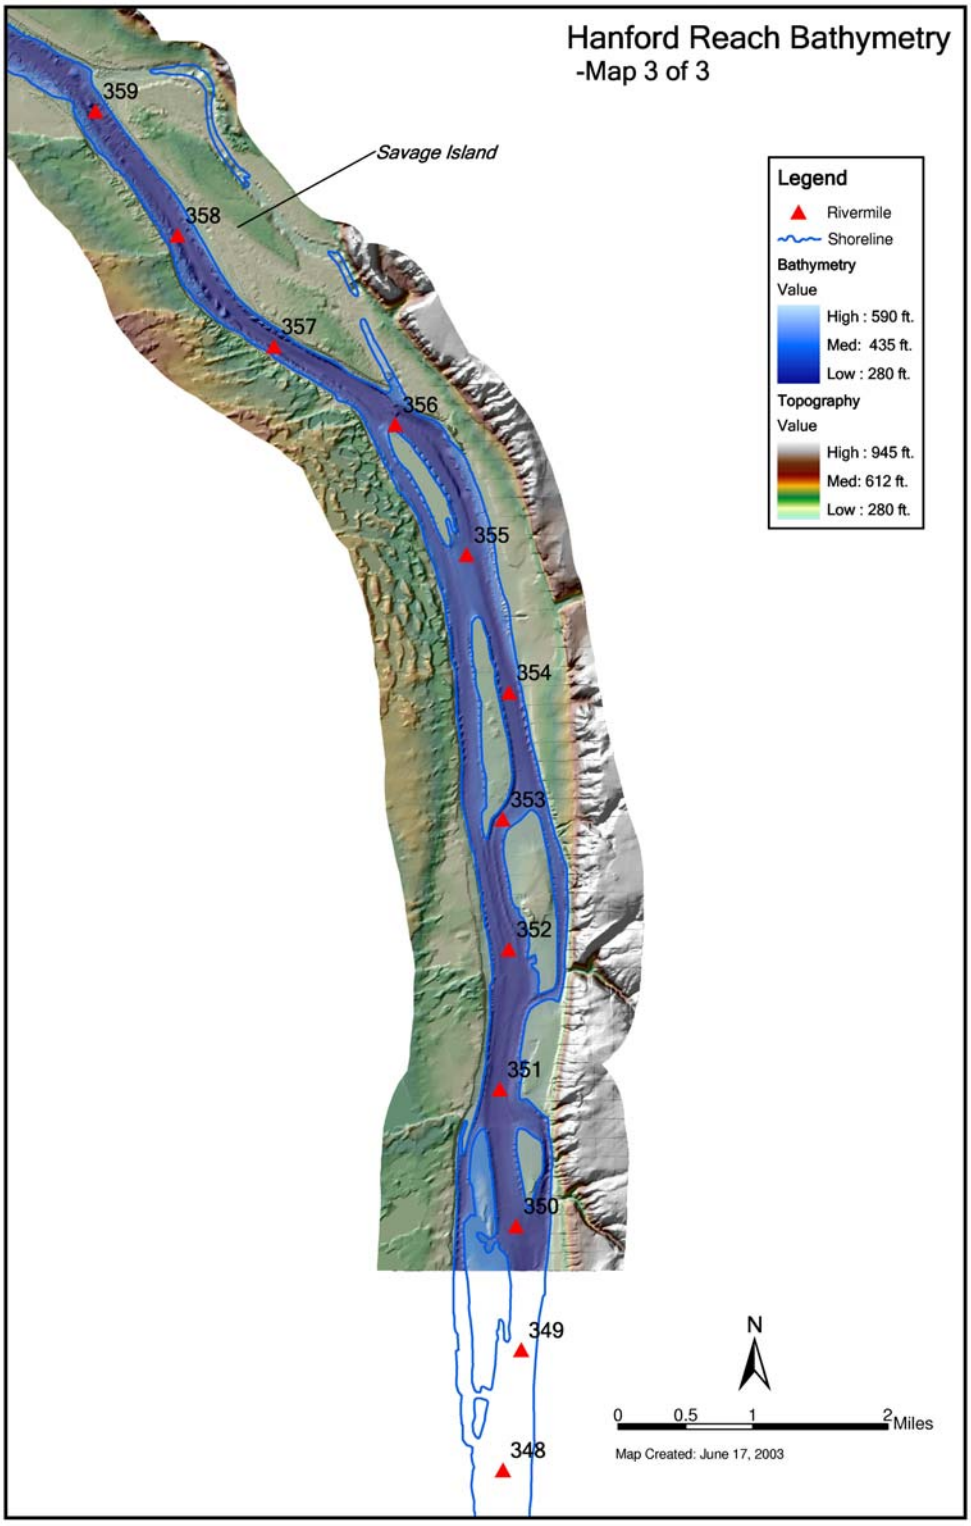

Figure 3. Updated Bathymetry, River Mile 350 to 358

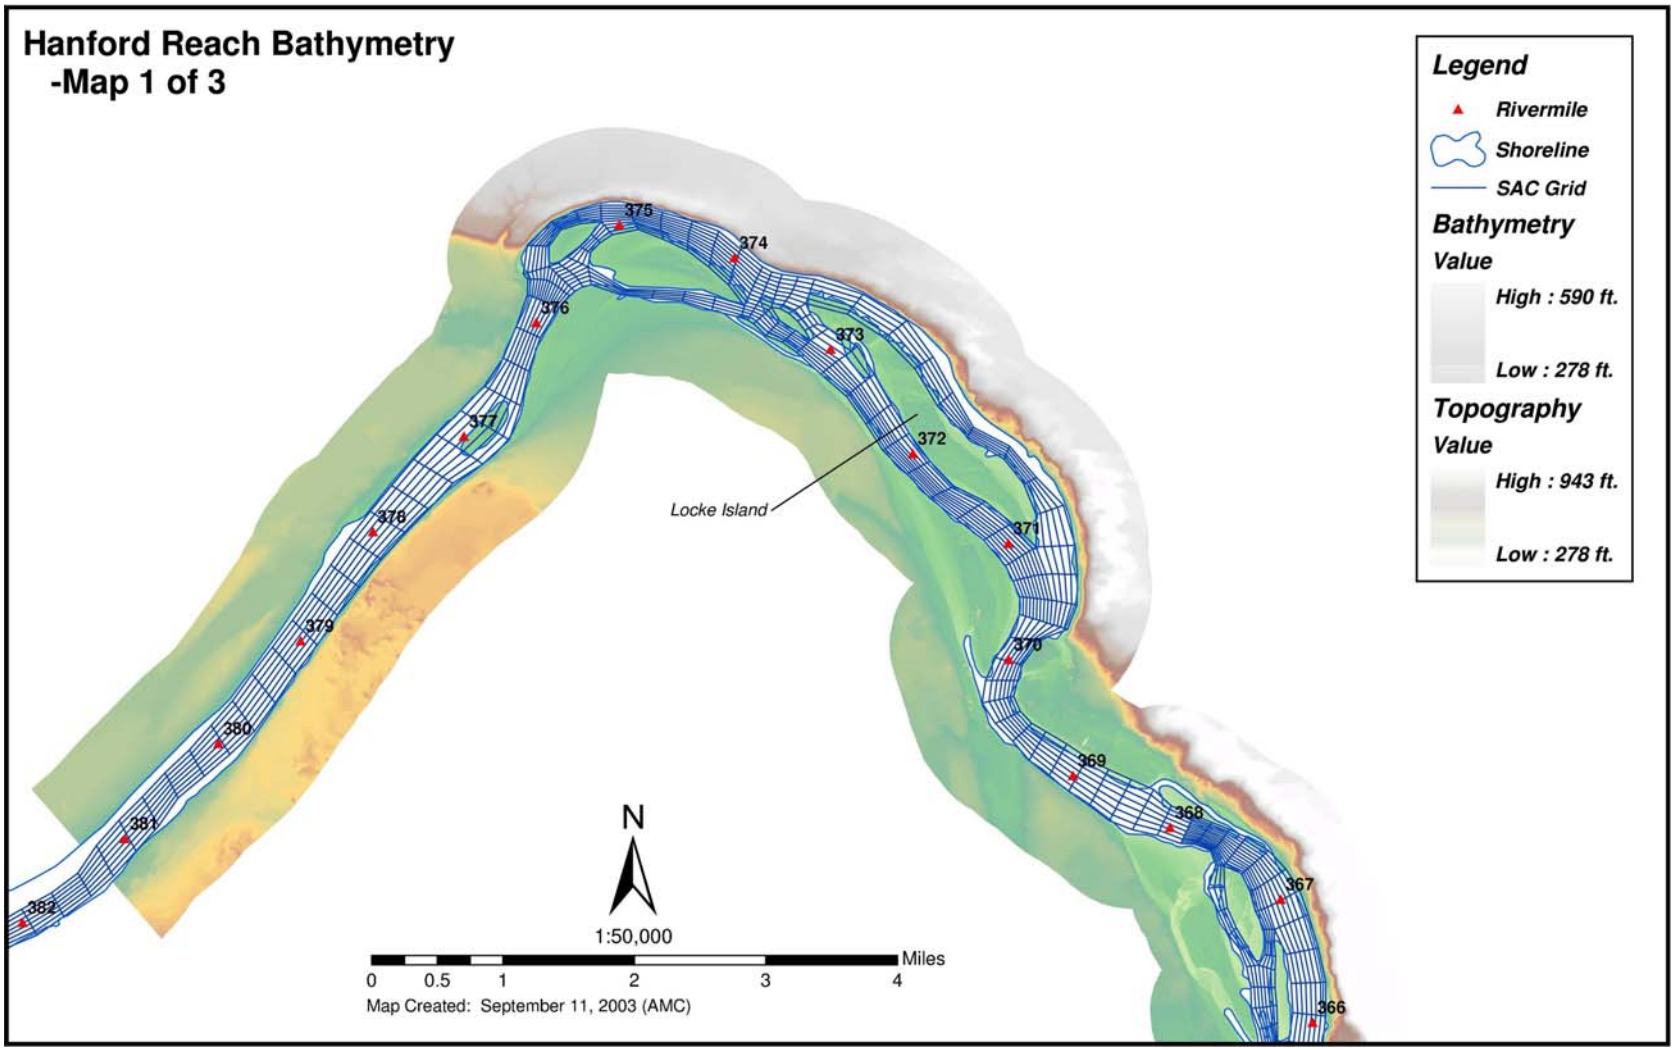

Figure 4. Computational Grid Example for the Upper Portion of the Study Area

3.1.4 Data Issues, Uncertainties, and Recommendations

The most notable technical issue with the bathymetry is that the areal extent of the river is limited to that of the simulated lowest flow channel because the current implementation of the model does not allow any cells to go dry. As a result, the model will underestimate the channel width at higher or flood flows and, therefore, may overestimate the depth in extreme cases.

The other technical issues result from gaps in geographic coverage of the data and limitations to the data collection technique. The SHOALS LiDAR data were only collected for a portion of RM 355 to 377 and can only penetrate into 4.6 meters (15 feet) of water. Consequently, there were data gaps in: areas not covered by the SHOALS survey or in areas too deep for LiDAR, or areas not included in the Pacific Northwest National Laboratory (PNNL) hydrosurvey data.[(a)] In these areas, a bathymetric data set was derived from the U.S. Army Corps of Engineers cross-section data. The cross-section data were interpolated in the stream-wise direction on an orthogonal grid system to fill the gaps between the cross sections. Only data from those areas not represented by any other source were used in the creation of a bathymetric surface.

3.2 River Discharge

A realistic representation of river discharge is important to simulate the hydrodynamic conditions within the river. Consequently, the choice of representative inflow conditions is crucial to obtaining the realistic transport of contaminants in the river.

3.2.1 Requirements

Two hydrodynamic inputs are required for MASS2: upstream discharge and the downstream water surface elevation. The downstream boundary of the model is the Columbia River near its confluence with the Yakima River. The water surface elevation is controlled by McNary Dam, so the only variable hydrologic data needed to run MASS2 are the flow of the Columbia River at the upstream end of the study area. This information is available through hydropower project operations records and U.S. Geological Survey (USGS) flow gaging data.

3.2.2 Data Gathering

Mean monthly flows were computed from the USGS Vernita Bridge gage data for use as model inflows. These monthly flows were not taken individually, but were grouped as flow years (i.e., January through December for each year), which preserved the character of the yearly hydrograph. The downstream stage was held at a constant 103.63 meters (340 feet) above sea level, the normal operating stage of McNary Dam.

(a) Unpublished data from Tim Hanrahan, Pacific Northwest National Laboratory, Richland, Washington.

3.2.3 Proposed Input Parameters

The historic Columbia River flow data at Priest Rapids Dam are shown in Figure 5. For the post-dam period (1975 to 2001), these data were grouped into a series of flow years from which the model selected at random. The probability density plot of the flow data is positively skewed (Figure 6).

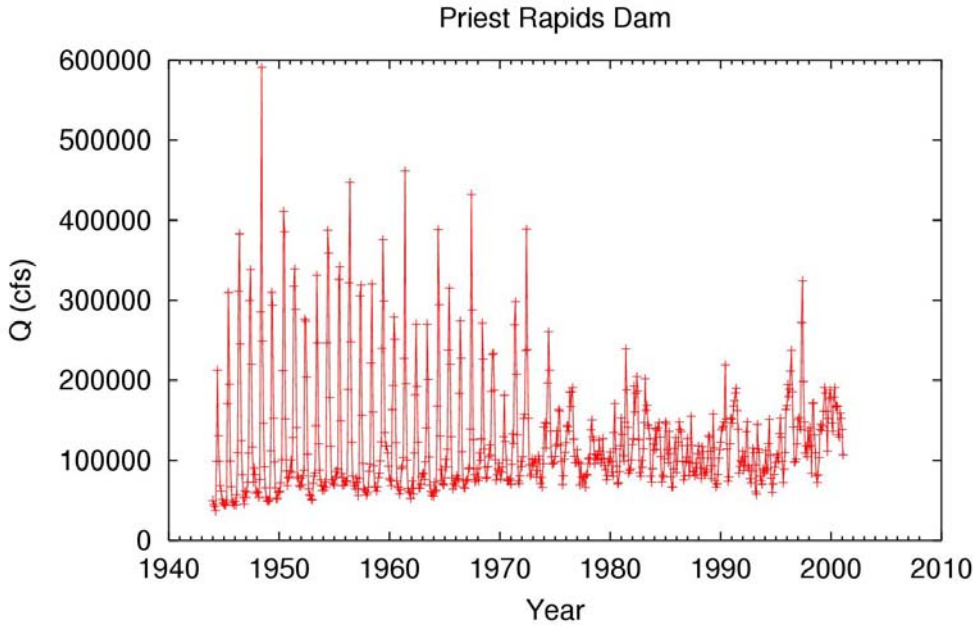

Figure 5. Columbia River Flow Data

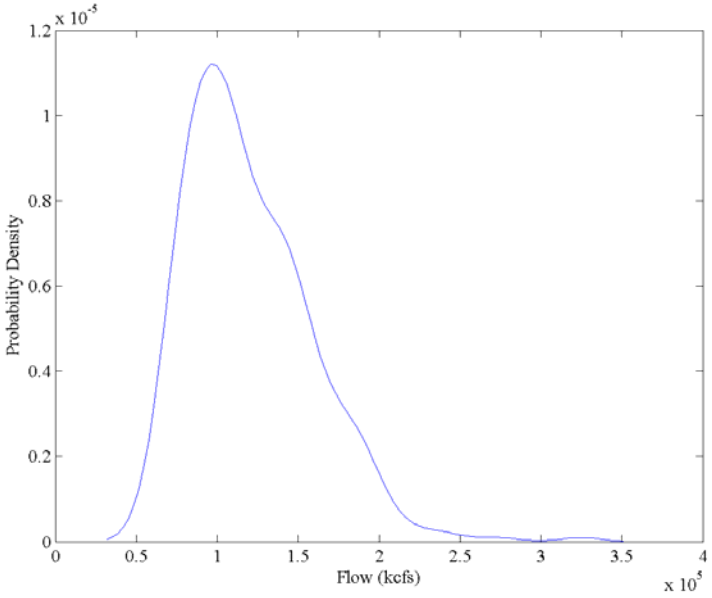

Figure 6. Probability Density Function of Priest Rapids Dam Flow Data for the Post-Dam Period (1975 to 2001)

3.2.4 Data Issues, Uncertainties, and Recommendations

The flow data are fairly straightforward and complete, although it does not reflect the daily flow fluctuations. The flow rate of the Columbia River in the Hanford Reach fluctuates significantly and is controlled primarily by releases from upstream dams. There are both seasonal and daily fluctuations in flow, which also cause fluctuations in river stage. Seasonal flows typically peak from April through June, during spring runoff from snowmelt, and are lowest from September through October. The seasonal change in average water level is up to about 2 meters (6.6 feet). Daily fluctuations in discharge are caused by releases from dams based on demand for power production. Because of these changes in flow, the river stage varies significantly over a short time period. Vertical fluctuations of more than 1.5 meters (4.9 feet) during a 24-hour period are common along the Hanford Reach (Poston et al. 2003). These fluctuations are not significant at the monthly output interval currently employed in the model, however. The flow data also represent only current conditions and the current conceptual model does not include future climate or hydropower changes that may affect the hydrograph, nor does it include extreme flood events.

3.3 Sediment

The characteristics of suspended and bed sediment are important for estimating the adsorption and subsequent fate and transport of contaminants in the study area. Many parameters are needed to accurately characterize the bed and suspended sediments.

3.3.1 Requirements

The bed sediment can be characterized for each river cell by material type, depth, median particle size, density, settling velocity, erodibility, and erosional and depositional critical shear values. The suspended sediment is characterized by these same properties, except that concentration (kg/m^3) is used to characterize the amount of suspended sediment, instead of the depth, as for bed sediment. These characteristics are estimated from available data or established relationships derived from empirical data.

3.3.2 Data Gathering

The background suspended sediment data were obtained from the USGS National Stream Water Quality Network (NASQAN) web site (http://water.usgs.gov/nasqan). Water quality parameters for the Columbia River water samples collected at Vernita Bridge were downloaded and used as model boundary conditions. Each dataset included additional information on numerous aspects of water quality including temperature, conductance, dissolved oxygen, pH, alkalinity, dissolved constituents, and suspended sediment concentrations. These data consisted of several measurements per year (typically quarterly) starting in 1996. All of the suspended sediment concentration data were averaged for each location to estimate the background suspended sediment concentration.

In past analyses, multiple bed depths had been assigned based on observed sediment size. The material types were derived from a geographic information system (GIS) coverage of the approximate spatial distribution of bottom material types, created by Tim Hanrahan from USGS data (Figure 7). When the sediment size was determined for the computational grid, it was observed that only 1% of the nodes

had a depth, based on past criteria, which would be different than 0.3 meter (1 foot) depth. Previous work had varied bed depths, in meters (feet), based on material types:

- Organic 0.3 (1.00)
- Organic-sand 0.3 (1.00)
- Organic-cobble 0.3 (1.00)
- Clay (soft) 0.9 (3.00)
- Silt 0.9 (3.00)
- Silt-sand 0.6 (2.00)
- Silt-gravel 0.3 (1.00)
- Silt-cobble 0.3 (1.00)
- Clay (hard) 0.9 (3.00)

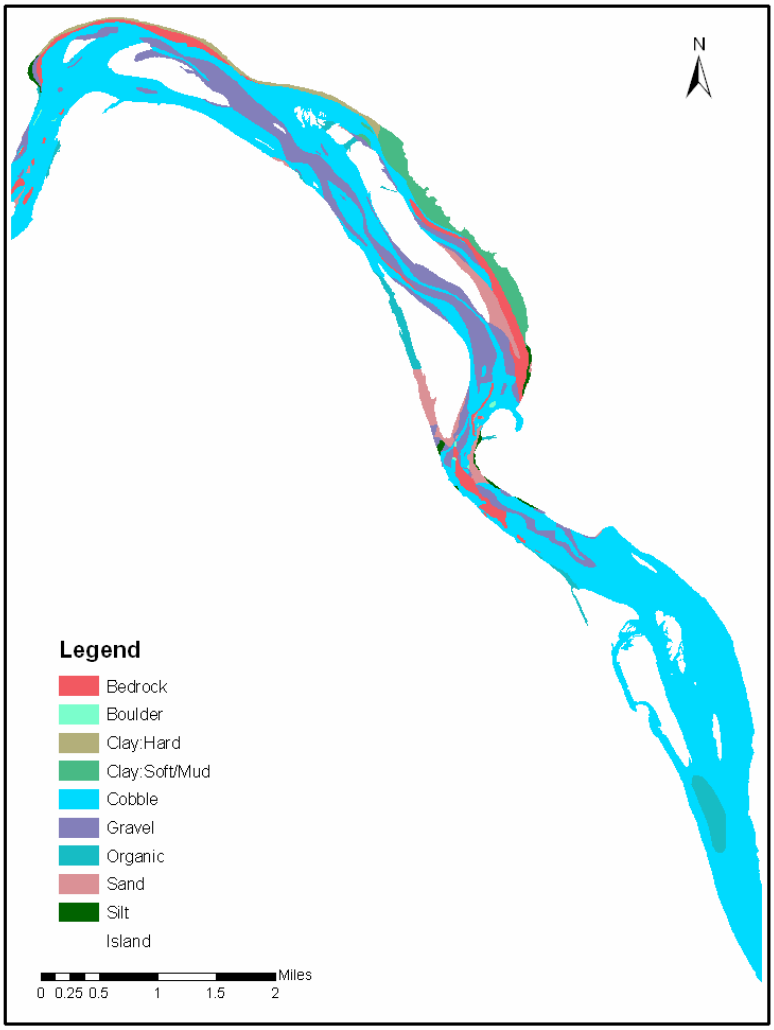

Figure 7. Sample of Color Coded Bed Material Coverage (Tim Hanrahan, Pacific Northwest National Laboratory, Richland, Washington)

More resistant or organic types have 1 ft depths. Consequently, all initial bed depths were set to 0.3 meter (1 foot). The presence of coarse or resistant sediments at the grid locations is reasonable as the river grid was restricted to locations that are inundated at all flows.

3.3.3 Proposed Input Parameters

Suspended sediment concentration in the Columbia River was set to a constant 3.75 mg/L. One sediment class with the following properties was used:

- Median particle diameter (d50): 0.003 cm (0.0001 feet)
- Solids density: 2,650 kg/m^3 (75.04 kg/ft^3)
- Settling velocity: 0.000010 m/s (0.000033 ft/s)
- Erodibility: 0.0
- Critical shear for erosion: 0.0073 kgf/m^2 (0.0015 lbf/ft^2)
- Critical shear for deposition: 0.0073 kgf/m^2 (0.0015 lbf/ft^2)

The river bed was represented as one sediment class that was 0.3 meter (1 foot) deep.

3.3.4 Data Issues, Uncertainties, and Recommendations

Almost all data gathered since the closure of the Hanford Site single pass reactors (early 1970s) have been for upper sediment (river/sediment interface). Only limited information is available for sediment grain size, total organic content, and sequestration by sulfide (Blanton et al. 1995; Patton and Crecelius 2001). Total organic content plays a large role in the variability of k_d values, which are discussed in Section 3.5.

The relative importance of sediment transport in the fate of in-river contaminants in the Columbia River is uncertain. The low concentrations of suspended and bed sediment moving in the Columbia River suggests that sediment may not be a high priority factor at this time. Therefore, in effort to minimize processing time, continuing to use one sediment class is recommended until the need for additional refinement is demonstrated with reliable data and analysis.

3.4 Groundwater Input (CFEST)

A series of scripts have been developed to allow the use of model outputs for groundwater and vadose zone flows and contaminants into the Hanford Reach of the Columbia River. The output locations for both models are mapped onto the MASS2 grid then time series of flows and transported variables used as inputs to MASS2.

3.4.1 Requirements

MASS2 receives input from the coupled fluid energy and solute transport (CFEST) groundwater module, the vadose zone model (STOMP), and in the case of reactor discharges, directly from the inventory module. Contaminant and water influx from CFEST is input to the bed sediment layer in MASS2 using output from the groundwater data translator (GWDROP), which matched the cells from the

CFEST model to the appropriate cells in the MASS2 computational grid. Vadose zone releases from STOMP are input into MASS2 with the VZDROP code. MASS2 then generates and outputs annual average concentrations of contaminants in the water column (dissolved and total sediment-sorbed) and in the bed sediment (pore water and total sediment-sorbed).

3.4.2 Data Issues, Uncertainties, and Recommendations

The data issues and uncertainties for the CFEST data are documented in Thorne (2004). The vadose zone model data issues and uncertainties are documented in Last et al. (2004).

3.5 Distribution Coefficients (k_d Values)

Partition coefficient (k_d) values are used to describe the adsorption of dissolved contaminants to ground, bed, and suspended sediment particles. This process affects both the bio-availability, and the fate and transport of contaminants. The basic k_d linear sorption isotherm model is

$$k_d = S / C_{aq} \tag{1}$$

where S is the sorbed concentration (or the concentration of the contaminant on the solid, Ci/kg), and C_{aq} is the concentration of the contaminant in the aqueous or dissolved phase (Ci/m^3). Suspended and bed sediment k_d distributions are estimated from available data for each contaminant. This linear model was deemed adequate for transport through the Hanford Reach (Cantrell et al. 2003).

A stochastic approach was taken to capture the wide range of values of k_d, reported in field and laboratory studies.

3.5.1 Requirements

MASS2 requires input of k_d for each transported particulate phase for use in the sediment-contaminant interaction portion of the model.

3.5.2 Data Gathering

Distribution coefficient estimates for the linear sorption isotherm model are site-specific because they are affected by numerous site-specific characteristics including pH, salinity, substrate size and composition, substrate cation exchange capacity, the presence of organics, the concentrations of competing ions, and redox potential. Although many partition coefficient studies exist, most pertain to groundwater or marine environments with relatively few applying to freshwater, aquatic systems. Of those, even fewer apply to the sections of the Columbia River affected by the Hanford Site. Available data for studies that involved fresh water, aquatic environments, and basalt substrates were examined to develop the most appropriate k_d distributions for our application (Kaplan and Serne 2000; Cantrell et al. 2003;). In consultation with Pacific Northwest National Laboratory geochemists, site-specific ranges of values of k_d for multiple contaminants for suspended sediments were developed (see Cantrell et al. 2003 for a discussion). The Environmental Stochastic Preprocessor (Eslinger et al. 2002) was developed to generate the needed variability in k_d as an input for the suite of MASS2 simulations used for the composite analysis.

3.5.3 Proposed Input Parameters

Partition coefficient values were represented with a number of basic distribution types based on the characteristics of each constituent. These distribution types include log normal, uniform, triangular, and constant. Partition coefficient distributions used for bed sediment, shown in Figure 8, consist of log normal distributions for selenium (Se), neptunium (Np), cesium (Cs), uranium (U), and strontium (Sr); a uniform distribution between 0 and 0.1 for carbon (C); and a triangular distribution for iodine (I). Also in Figure 8, the median k_d values occur at 0.5 cumulative probability for the lognormal distributions and the distribution used for technetium (Tc) was generated so that half of the values would be simulated as zero. Distributions for tritium and chlorine do not appear in Figure 8 because these constituents were assigned constant k_d values of zero, indicating that they do not adsorb to sediment. For strontium, technetium, iodine, and uranium, suspended sediment k_d distributions are believed to differ from those used for bed sediment. Distributions for these constituents, shown in Figure 9, were all log-normally distributed.

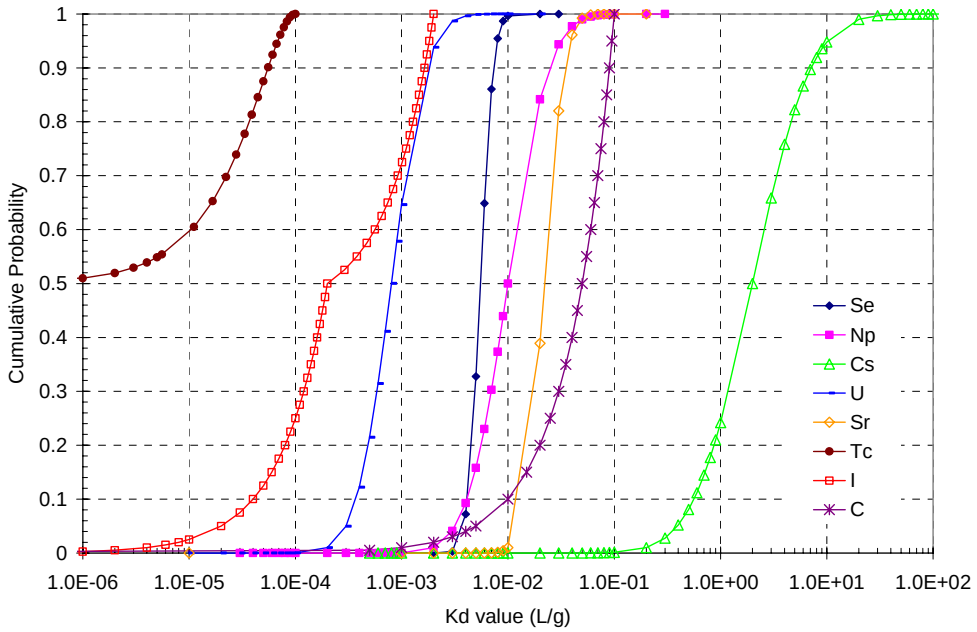

Figure 8. Cumulative Probability Distributions of k_d Values for Bed Sediment from Which Model Input was Stochastically Derived. (Note that the lower k_d limit for Tc, I, and C is zero, which cannot be plotted on a log scale.)

3.5.4 Data Issues, Uncertainties, and Recommendations

Uncertainties in the k_d values were determined by using values derived stochastically from carefully designed distributions for each constituent that span the range of possible values. These distributions should be refined as new information becomes available.

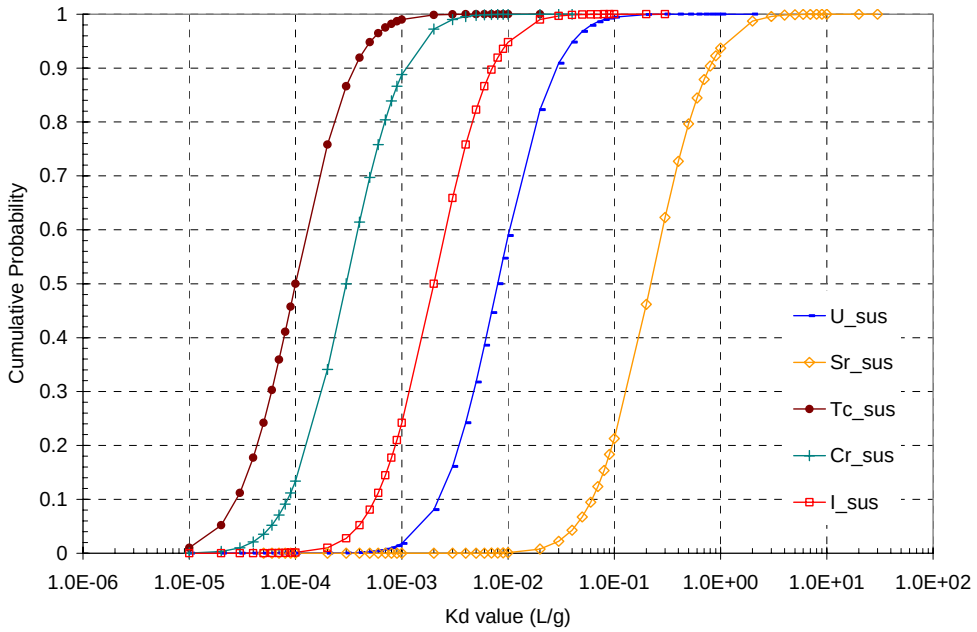

Figure 9. Cumulative Probability Distributions of k_d Values in Suspended River Sediment for Use in the Stochastic Determination of Model Input. Constituents not shown are unchanged from bed k_d distributions.

3.6 Radionuclides

The concentrations of radionuclides in Columbia River water and sediment samples collected (or modeled) at both background locations and locations potentially affected by Hanford contaminants are needed for the composite analysis. The requirements, data gathering methods, proposed model input parameters, and other data issues are discussed this section.

3.6.1 Requirements

Background values of radionuclide concentrations are necessary for MASS2 to simulate contaminant fate and transport. Background concentrations of dissolved radionuclides in the Columbia River were determined from available data for contaminants with measurable background levels. Background concentrations of radionuclides adsorbed to sediment were either estimated from measured data or computed from the dissolved concentrations assuming equilibrium partitioning.

Dissolved and sorbed radionuclide concentrations in sections of the Hanford Reach affected by Hanford Site contaminants are also necessary for MASS2 to simulate contaminant fate and transport. Concentrations of radionuclides in this section of the Columbia River were determined from available data with measurable levels. Concentrations of radionuclides in sediment were either estimated from measured data or computed from the dissolved concentrations assuming equilibrium partitioning. Radionuclide concentrations in reactor discharges during operational years (1944 to 1971) are not incorporated at this time.

3.6.2 Data Gathering

Surface water and sediment background radionuclide data for the initial model runs were obtained from 5-year geometric means for 1990 to 1995 taken from the Columbia River Comprehensive Impact Assessment (CRCIA) Project (DOE 1998). This data set is based on a data compendium (Eslinger et al. 1994) and a data volume (Miley et al. 1997) that were produced for CRCIA. The data compendium provides a collection of references, data source, descriptions of data formats, and a discussion of the search process.) These data are discussed further and presented in the next section and are included in the companion compact disk (CD) issued with this report.

Additional radionuclide data from the Hanford Environmental Information System (HEIS) database has been summarized and are included in the companion CD issued with this report. The majority of the radionuclide data were collected for the Hanford Site's Surface Environmental Surveillance Project with the sampling locations, sampling and analytical methods, and results reported annually (e.g., Poston et al. 2003; Bisping et al. 2003).

3.6.3 Proposed Input Parameters

Radionuclide inputs were based on primarily on data from the HEIS database. This information been summarized in Tables 1 through 3 to provide examples of the data (see CD issued with this report).

Most of the available data for radionuclides in the water column is for total (unfiltered) water samples with limited information about dissolved and particle associated fractions. There was a reasonable amount of dissolved and particle associated data from the continuous filter/resin systems operated by the Hanford Site Surface Environmental Surveillance Project (e.g., Poston et al. 2003) at Priest Rapids Dam, the 300 Area drinking water intake, and the Richland pumphouse. Dissolved/particle data were available for iodine-129, plutonium isotopes, and gamma-emitting sorbed radionuclides; however, a significant portion of the data were reported as less than the detection limit for at least one fraction. Another potential source of information on sorption is available from metals data (filtered and unfiltered) collected from Columbia River transect water samples. The metals data are reported in the Hanford Site Environmental Surveillance Data Reports (e.g., Bisping 2003), with results for samples collected after 2002 available in the HEIS database.

3.6.4 Data Issues, Uncertainties, and Recommendations

Most of the available water data for radionuclides were for total (unfiltered) water samples with limited information on dissolved and particle associated fractions. No data were available for chorine-36 for sediment or water samples. Data analysis is complicated for some radionuclides because a significant portion of the results are reported as undetected values.

Table 1. Examples of River Water and Sediment Data Available from the Hanford Environmental Information System (attached to companion CD)

Media	Locations	Dates	Analytes	File Name
River water	Multiple On/Off Site, VB, Regional	1970 - 1989	Cr6+, Cs-137, I-129, Pu-iso, Sr-90, Tc-99, U-iso, Particle/Dissolved	70-89 all water

4.0 Conclusions and Recommendations

River discharge estimates were adequate to the current task of running the simulation model at a monthly time interval. Daily and hourly flow data are available if the time is reduced in the future. A good bathymetric grid has been developed that provides increased resolution where necessary. Sediment data are the least available, but there is little evidence demonstrating an immediate need for additional resolution on this model component. Partition coefficient values have been broadly defined with carefully defined distributions based on the best available data, and stochastically incorporated into the model. Groundwater inputs are defined by the groundwater model results. Substantial data on radionuclide background levels and river inputs exist, and additional information is continually becoming available through programs such as the HEIS and Hanford Site Surface Environmental Surveillance Project.
