1.0 Introduction

An emission and air dispersion modeling effort was conducted relative to proposed demolition activities for the 224-U and 224-UA Buildings. The 224-U and 224-UA Buildings (Figure 1.1, 1.2, and 1.3) are located in the U-Plant UO_3 complex in the 200 West Area of the Hanford Site. These facilities converted uranyl nitrate hexahydrate (UNH), a product of Hanford's Plutonium-Uranium Extraction (PUREX) Plant, into uranium trioxide (UO_3). The UO_3 powder was shipped offsite for conversion to uranium metal for nuclear reactors. The UO_3 Plant consists of two major buildings: the 224-U building (built in 1943 as part of the plutonium processing construction, but converted to uranyl nitrate concentration, conversion processing); and the 224-UA building built in 1956 to house new continuous calciners. The 224-U building houses the concentrating and nitric acid recovery equipment. In addition to the calciners, the 224-UA building houses the powder-handling tower and the UO_3 powder packaging machinery (used to load T-hoppers). During deactivation in 1993, most of the radioactive material was removed; the remaining is primarily residual uranium tri-oxide dust in the calciners and powder handling systems. The U.S. Department of Energy (DOE) and CH2M HILL Plateau Remediation Company (CHPRC) plans call for demolishing the structure in late 2009.

Pacific Northwest National Laboratory (PNNL) supports the demolition planning effort by making engineering estimates of potential releases for various demolition alternatives. Air-dispersion modeling has been conducted using those release rates to provide information on the location and levels of radioactivity. Similar efforts for planning the demolition of a highly contaminated structure are reported by Droppo et al. (2007). The UO_3 plant demolition being modeled in this analysis differs from the previous efforts in that this facility only has uranium contamination versus the previous efforts for facilities where plutonium was the contamination of concern.

The facilities surrounding the UO_3 complex, particularly the 221-U canyon building, have the potential of affecting dispersion patterns through various meteorological phenomena, including building wake effects. Atmospheric dispersion calculations have been run using the American Meteorological Society/Environmental Protection Agency Regulatory Model (AERMOD) (EPA 2008), a computer code developed by the U.S. Environmental Protection Agency (EPA). This code calculates dispersion patterns considering building wake effects and other meteorological phenomena. The results from the AERMOD calculations are being used to plan demolition activities that will keep potential contamination within the boundaries established for the project contamination area.

The 224-U building is 197 feet long, 60 feet wide, and 40 feet tall. The building is divided along its length by a 12-inch-thick concrete shield wall into a gallery side and a canyon side. The gallery side is a three-story reinforced concrete frame structure with concrete floor and roof slabs. Exterior and interior walls are non-reinforced, 8-inch concrete blocks. The roof, supported by concrete beams, is a flat reinforced concrete slab between 5 and 12 inches thick. The canyon side, constructed of 12-inch-thick reinforced concrete walls, is also three stories high. The canyon is divided into six cells and the Luckey pot room. Each cell is separated by a concrete wall that extends part way (15 feet) toward the ceiling. A portion of C-cell is the only part of the 224-U building that extends below grade. In 1956, the 224-UA building (housing six electrically heated agitated-trough calciners designed for continuous operation) was constructed to process the uranyl nitrate product from the PUREX Plant. The 224 UA Building is approximately 75 feet long and 67 feet wide. The floor slab and footing are reinforced concrete. Equipment footing and supports are reinforced concrete pier columns with steel "I" beam framing. The

outside walls consist of insulated metallic-coated steel panels. The ground floor consists of six two-story cells. The continuous calciners are located on the second floor of these cells. The five-floor-high tower section of the building located over the load-out room was used to handle the UO_3 powder. The tower contained two primary bag filters, two cyclones, and a storage bin. The 224 UA Building roof consists of steel panels covered with insulation and built-up roofing material. Numerous pieces of equipment and ducting, including the 296 U-2 and 296 U-14 exhausters, are located on the roof.

UO_3 powder handling was conducted using high-volume air vacuum transport. The vacuum systems had substantial ducting and bag and high-efficiency particulate air (HEPA) filters at the exhaust end to retain any UO_3 dust that escaped the powder-handling system. The old powder-handling system consists of a tower and a pair of bag filter housings, with associated ducting, on the south-west end of the 224-U building. There is a pair of bag filter housings on the north-west side of the 224-UA building, with associated ducting and a large HEPA filter on the roof.

Debris will be disposed of at the Environmental Restoration Disposal Facility (ERDF) in the 200 Areas.

Figure 1.1. The 224-U and 224-UA Buildings, Which Are in a Location Surrounded by Other Large Structures, Complicating Atmospheric Dispersion Modeling. The location of the UO_3 complex within the buildings is highlighted.

Figure 1.2. Cross-Section of 224-U Building

Figure 1.3. Cross-Section of the 224-UA Building

The most-contaminated equipment associated with 224-U is a pair of bag filter housings and a powder storage bin outside the southwest side of the building, and their associated ducting. The most-contaminated equipment associated with the 224-UA building is a pair of bag filter housings on the northwest side of the building, in the narrow gap between 224-U and 224-UA, a HEPA filter on the roof, and their associated ducting. The calciners in 224-UA also contain a substantial quantity of UO_3 powder.

There is a minimal working distance between the 224-U building and the 221-U canyon building of about 150 feet (50 m).

This report covers the summary of analysis and results of modeling scenarios (Chapter 2.0), a description of the demolition operations considered (Chapter 3.0), a description of the source-term analysis (Chapter 4.0), and a summary of the atmospheric dispersion and deposition modeling used (Chapter 5.0). The references are in Chapter 6.0.

Computation details and model input/output listings are in the Appendices. The source term computation is in Appendix A, the emission rate computation in Appendix B, and the AERMOD input/output listings for the combined demolition of both buildings are in Appendix C.

2.0 Analysis and Results Summary

Atmospheric dispersion modeling has been conducted in support of the demolition of the 224-U and 224-UA buildings using estimated release rates to provide information on the location and levels of radioactive contamination that may be expected. The facilities surrounding the UO_3 plant have the potential to affect dispersion patterns through various meteorological phenomena, including building wake effects. Hourly meteorological data collected over a 5-year period were used to examine the effects of wind speed, direction, and stability on projected concentrations of contaminants in air and deposited on nearby surfaces.

The radioactive contamination of concern for UO_3 plant demolition is largely located in powder handling systems associated with, and largely outside of, both buildings. A radionuclide inventory was provided by CHPRC (2008).

CHPRC (2008) also indicates that the demolition activities will occur in two distinct phases. Initially, the 224-U building will be completely demolished and removed. Then the 224-UA building will be demolished and removed. The modeling is thus conducted for two time periods: a 20-working-day period for 224-U, and a separate 20-working-day period for 224-UA. The overall period is anticipated to fall within the periods of July-September and /or October-December 2009.

2.1 Analysis

EPA's AERMOD computer code is used to estimate atmospheric dispersion and deposition of the released radioactive materials in the immediate vicinity of the demolition activities. These *hour-by-hour* estimates for the time periods that demolition is planned included the effect of the nearby buildings on the air flow. These estimates are made for weather conditions that are representative of the expected demolition period. The air concentrations and deposition rates are modeled for an array of receptors covering the demolition site and surrounding area. Both average and peak values of air concentrations are evaluated with modeling results reported as DAC for air concentrations and dpm per 100 cm^2 for deposition.

The modeling analysis defines the potential levels of air and soil exposures from the proposed demolition activities. Potential air exposures are defined in terms of 1) the distribution of occurrences of peak concentrations at a control boundary and 2) spatial patterns of average and peak concentrations. The potential soil exposures are defined in terms of spatial patterns of total deposited concentrations of alpha and beta/gamma emitting materials.

Using these methods, emission and air-transport computations were made to assess the potential concentrations from different sets of demolition assumptions. The analysis process consisted of three steps:

- Step 1. Estimate the emission rates for the proposed demolition activities—Step 1 starts with an estimate of the amount of contamination in the structure, what form it is in, and where it is located. Demolition methods and associated activities are identified in this step. These data are combined to generate estimates of emissions during the demolition activities.

- Step 2. Compute the airborne and deposited concentrations—Step 2 takes the emission rate estimates from Step 1 and produces estimates of environmental concentrations. An assumed 1-hour release is used to define potential peak exposures. The main products are hourly peak air concentrations and hourly peak (equivalent to total) deposition.
- Step 3. Determine if the potential concentration levels are acceptable—Step 3 uses standards to evaluate the viability of the demolition option that has been modeled. For air exposures, a derived air concentration limit of 12 (DAC)-hours per week is used. For deposition, a limit 1000 dpm/100 cm² of uranium is used. If none of the locations within the selected areas show values that exceed these limits, then the demolition is deemed clearly viable.

2.2 Results

The worst case for the occurrence of the highest air concentrations is for the majority of the release to occur over a short time period. To address this possibility, the potential peak hourly concentrations over the planned work periods were modeled using the estimated emission rates.

To evaluate the potential exposure levels from the planned demolition activities, the local patterns of air concentrations and soil deposition were computed for each hour of the appropriate time periods using 5 years of recent meteorological data. Although the demolition is planned to occur either in the July to September or the October to December 2009 time frame, the potential peak concentrations were computed for entire years of data to provide an analysis that will produce bounding values no matter when the demolition occurs at this site. On each day, the activities are assumed to occur during the day shift.

Because none of the modeled values exceeded the air and soil concentration limits, it was unnecessary to generate frequency of occurrence plots for air and soil concentrations. That is, the gridded modeling results show that frequency of occurrence of exceedances will be zero at all control boundaries.

The analysis showed that open-air demolition of the UO₃ Plant buildings is a viable option. The planning for open-air demolition includes definition of the measures that will be taken to minimize air emissions during the demolition activities. The modeling results presented here are closely tied to the details of how the demolition is to be conducted.

2.3 Discussion

The results indicate that the radiological exposures from the planned demolition efforts will be below the designated limits for air and soil exposures.

3.0 Demolition Analysis

The potential emission rates associated with proposed demolition activities are estimated based on specific methods of execution. This section provides a definition or description of those activities including the assumptions and approximations that are required to provide a context for the demolition.

3.1 Existing Radionuclide Inventories

The radioactive contamination of concern for the UO₃ complex building demolition is located within process equipment remaining in and adjacent to the buildings.

A conservatively estimated inventory provided by CHPRC (2008) is given in Table 3.1. The inventory is assumed to consist of residual dust adhering to the inner surfaces of the machinery, ducts, and filter housings. The dust is assumed to be UO₃ powder, with a density of 7.29 grams/mL and 5-micron particle size.

Demolition of the buildings, although different in specifics, is assumed to be similar with three main components: removal of the external UO₃ powder-handling systems, demolition of the main parts of the structures, and demolition of the calciners and their associated equipment.

For this analysis, the uranium is assumed to be enriched to 1% ²³⁵U. The material has been separated for nearly 20 years; therefore, it is assumed that the short-lived uranium progeny are in equilibrium with the uranium isotopes. As a result, 1 gram of UO₃ powder is assumed to contain:

²³⁸ U, ²³⁴ Th, ^{234m} Pa	3.33E-7 Ci
²³⁵ U, ²³¹ Th	2.14E-8 Ci
²³⁴ U	5.24E-7 Ci (Slightly enriched from equilibrium with ²³⁸ U.)

The uranium isotopes all emit alpha particles; the progeny are all beta/gamma emitters. Thus, one gram of UO₃ powder/dust will contain 20,180 dpm.

3.2 Demolition of the UO₃ Powder-Handling Systems with Multiprocessor

At the initiation of work, the most-accessible equipment on the outsides of the buildings is assumed to be removed first. For both buildings, this includes the ducting, bag filter housings, and for 224-U, the storage hopper.

The modeling analysis requires a definition of representative demolition activities and a plan for performing those activities. The equipment is removed using a large excavator to manipulate a multiprocessor. This device will separate the components into manageable sizes and lower them to the

ground. It is anticipated that one working day will be required to dismantle the external equipment and a second working day to package it into ERDF boxes.

Misting, water, and fixatives will be used throughout the demolition process and load-out to minimize airborne contamination spread. All demolition and load-out will only occur when sustained wind speeds are less than 12 miles per hour.

Table 3.1. Conservative Inventory of Radionuclides in UO₃ Complex, Grams

224-U Building		
Location	Quantity (lbs)	Quantity (g)
Primary Bag Filters X-3	85	38600
Hopper X-3	80	36300
Powder Handling Cyclone X-5	20	9070
Storage Bin X-7	180	81600
Secondary Bag Filters X-11	40	18100
Hopper X-11	50	22700
Glass Wool Filter X-12	18	8170
Total	473	215000
224-UA Building		
Location	Quantity (lbs)	Quantity (g)
Zero ft Level Pickup Bins G-M	12	5440
Calciners G-M	300	136000

Storage Bin X-26-1	28	12700
Primary Bag Filters and Pipes X-28-1 & -2	140	63500
X-28's Hopper	50	22700
Secondary Bag Filters and Pipes X-29-1 & -2	140	63500
X-29's Hopper	50	22700
Discharge to HEPA Filters and HEPA Filters	130	59000
Total	886	402000

Rubble produced during demolition will be loaded out with front-end loaders or the thumb-and-bucket on the excavator. The rubble will be picked up and placed into transfer boxes at various locations within the excavation. No additional containment structures (tents, etc.) are assumed for this activity; however, like the demolition itself, misting, water, and fixatives will be used to minimize airborne contamination spread. All loading will only occur when sustained wind speeds are less than 15 miles per hour. The 12-mph wind speed only applies when disturbing the UO₃-contaminated equipment and debris.

3.3 Demolition of the Main Building Structures

The walls and roofs are to be demolished from the top down with a large excavator to manipulate a multiprocessor. This device will crush the concrete into roughly 1-foot pieces. (The ERDF acceptance criteria include requirements that the pieces be sized into less than 1-foot cubes.) Misting, water, and/or fixatives will be used throughout the demolition process and load-out to minimize airborne contamination spread. It is assumed that demolition of the 224-U and 224-UA building superstructures will take 8 working days each. All demolition and load out will only occur when sustained wind speeds are less than 12 miles per hour.

Rubble produced during demolition will be loaded out with front-end loaders and the thumb-and-bucket on the excavator. The rubble will be picked up and placed into transfer boxes at various locations within the demolition zone. No additional containment structures (tents, etc.) are assumed for this activity; however, like the demolition itself, misting, water, and fixatives will be used to minimize airborne contamination spread. All loading will only occur when sustained wind speeds are less than 15 miles per hour.

3.4 Demolition of the Calciners and Associated Equipment

The continuous calciners are located on the second floor of the 224-UA cells. The calciners are large pieces of mechanical equipment developed and designed at Hanford. They had large troughs with paddle agitators that essentially turned and mixed the UNH throughout the process. The calciners used air as an agitator and maintained a seal between the calciner and the powder pickup bin, while passing a continuous stream of UO_3 . The calciners produced a pebbly product that consisted of spheres with an average diameter of 200 microns; the residual is assumed to be smaller (about 5-micron activity median aerodynamic diameter [AMAD]) dust particles.

It is assumed that the demolition of the calciners, because they are large, robust pieces of concrete and steel, will take 10 working days. They will be removed in large sections using a large excavator to manipulate a multiprocessor, with minimal disruption of the internal components of the calciners, although they may have to be broken into large segments for handling and disposal.

Rubble produced during demolition will be loaded out with front-end loaders and/or the thumb-and-bucket on the excavator. The rubble will be picked up and placed into transfer boxes at various locations within the demolition zone. No additional containment structures (tents, etc.) are assumed for this activity; however, like the demolition itself, misting, water, and fixatives will be used to minimize airborne contamination spread. All sorting of contaminated debris will only occur when sustained wind speeds are less than 15 miles per hour.

3.5 Demolition Schedule Assumed for Modeling

The basic plan is that all demolition will occur between October and December 2009.

A generic daily schedule was provided by CHPRC staff. This generic schedule provides an indication of the hours of each day in which activities occur and the approximate fractions of time spent in demolition, load-out, and other procedures that result in emissions. This general schedule will be run

5 days per week, with one 10-hour shift per work day. It is assumed that actual demolition activities will take place during only about 8 hours per work day.

The demolition activities are thus assumed to be conducted for two time periods: a 20-working-day period for 224-U and a second 20-working-day period for 224-UA. It is assumed that the 224-U building outside equipment will be removed first, and then the relatively-uncontaminated remainder of the 224-U building. The external equipment on the 224-UA building will be removed, followed by the building superstructure, and then the calciners and supporting foundations and associated equipment underneath.

4.0 Source-Term Analysis

The radiological consequences have been established using the methods discussed in DOE-HDBK-3010-94 (DOE 1994). This approach was successfully used for the 233-S Building (AlphaTRAC 2003a, 2003b), 232-Z Building (Droppo and Napier 2006), and 105 KE Basin (Napier et al. 2008) and is particularly appropriate for facilities such as the UO₃ Plant buildings, where the dose from the inhalation pathway will dominate the overall dose.

4.1 Analysis Methodology

The source term may be quantified using the five-factor formula.^(a)

$$ST = MAR * DR * ARF * RF * LPF \quad (4.1a)$$

$$ST = MAR * EF \quad (4.1b)$$

where

Source term (ST)	=	the total quantity of respirable material released to the atmosphere during the demolition
Material-at-risk (MAR)	=	the total quantity of radionuclides (in grams or curies of activity for each radionuclide) available to be acted on by a given physical stress
Damage ratio (DR)	=	the fraction of the MAR actually impacted by the demolition conditions
Airborne release fraction (ARF)	=	the fraction of a radioactive material suspended in air as an aerosol and thus available for transport due to a physical stress from a specific activity
Respirable fraction (RF)	=	the fraction of airborne radionuclides as particles that can be transported through air and inhaled into the human respiratory system and is commonly assumed to include particles 10-μm aerodynamic equivalent diameter (AED) and less
Leak path factor (LPF)	=	the fraction of the radionuclides in the aerosol transported through some confinement deposition system (e.g., facility rooms, ductwork) or filtration mechanism (e.g., HEPA or sand filters).

The last four factors are sometimes combined into an emission factor (EF) to be multiplied with the MAR, where $EF = DR * ARF * RF * LPF$.

For these analyses, the MAR is defined as the inventory that is on the surface area being demolished. While it is permissible to exclude material forms that are considered to be unaffected from the MAR, experience suggests that for these forms, the DR is usually best set to zero for the release mechanism. The overall result using either approach is the same. However, by assigning DR values to each combination of the inventory form and release mechanism, there is the expectation that each credited form is also reviewed against secondary events and, therefore, less likely to be overlooked.

(a) The following discussion is adapted from *GENII Computer Code Application Guidance for Documented Safety Analysis*, DOE-EH-4.2.1.4-Interim-GENII, Rev. 1, U.S Department of Energy, Washington, D.C.

Radioactive contamination emissions (STs) have been calculated by release mechanism and demolition area for on-shift and off-shift activities. The emissions from the applicable sources have been combined to provide emission estimates for each day from each demolition area.

In the following sections, each term is discussed in the order seen in the source-term equation.

4.1.1 Material at Risk

The material at risk for any unit operation is the quantity of the radioactive inventory that is exposed for demolition over a 1-day period. MAR values are calculated assuming no fixatives are used.

The building structural materials demolished using the multiprocessor will be crushed or torn into rubble pieces during removal. The contamination is largely dust and particulates from the UO_3 calcining and powder-handling operations. The particle-size distribution of the UO_3 dust will be assumed to be 5 microns for evaluating transport, dispersion, deposition, and dosimetry.

Some contamination that could be subject to resuspension during off-shift periods is calculated for each demolition area. However, the planned procedure is to have the working surfaces covered with fixatives sprays, etc. Given these assumptions, there is no removable MAR considered subject to resuspension during each off-shift period.

4.1.2 Damage Ratio

The main components containing UO_3 powder are the powder-handling ducts, cyclones, hoppers, and filter (bag and HEPA) housings. It is assumed that these components are contaminated with dust on their inner surfaces. Removal with a multiprocessor will result in tears and holes in these pieces. It is assumed that 10% of the contained UO_3 powder will be released through holes and tears in the metal.

A multiprocessor will be used to demolish the buildings and to break the calciners into large parts. The MAR is assumed to be evenly distributed over the entire contaminated area being worked on (wall segment, floor area, etc.). The DR is that portion or percentage of the contaminated area acted on by the shear force, or the portion or percentage of the contamination acted on by shear forces. Jaws are assumed to fracture, crush, spall, or otherwise impact the surface being sheared. Because the buildings are of concrete block and reinforced concrete construction, the equipment is assumed to reduce essentially the entire portion of wall or floor being worked on to small pieces. Half of the surfaces are assumed to be rubblized during demolition operations (factor of 0.5). This value is greater than that used for the 232-Z Building, which was based on pulling down a block wall (0.05—Droppo and Napier 2006), and slightly smaller than that used for the analysis of the reinforced concrete walls of the 233-S Building (0.6—AlphaTRAC 2003a). Until placed in the ERDF boxes, all of the material rubblized will remain piled on the ground and moistened with water and routinely sprayed with fixatives.

The calciners are a special case. These machines are large, solid pieces with contamination on the inside surfaces. Because they are too large to simply remove, they must be broken into smaller pieces, but they will not be completely rubblized. Therefore, it is assumed that 10% of the surface contaminated with UO_3 will be damaged.

4.1.3 Airborne Release Fraction

Powders released from the ducts, cyclones, hoppers, and filter housings will be released into the air; they will fall to the ground under the work areas. The DOE handbook (DOE 1994) discusses several sets of experimental observations directly related to airborne releases from falling powders. Sutter et al. (1981) observed UO_3 and TiO_2 powders freely falling into moving air from a height of 3 meters. They report a release fraction of about 2×10^{-3} . Ballinger et al. (1988) developed a model for releases from falling powders, wherein

$$\text{ARF} = 0.1064 (M^{0.125}) (H^{2.37}) / \rho^{1.02} \quad (4.2)$$

where M = mass spilled, kg
 H = height of spill, m
 ρ = density, kg/m^3 .

For a 1-kg release of UO_3 powder, of density 7.29 g/mL (CRC Handbook 1986), from a height of 3 meters, the estimated ARF using this equation is 1.6×10^{-4} . Plinke et al. (1991) reports an ARF approaching 10^{-3} for applicable powders; this reference also indicates a large decrease in ARF with increasing moisture content—thus confirming that misting will be helpful in reducing emissions. Once the powders fall to the ground, the ongoing demolition activities will result in rubble falling onto it. The DOE Handbook (ref., page 4–85) indicates an ARF of about 10^{-3} for suspension caused by objects falling into powder, with release fractions of up to 10^{-2} (but corrected for burial by fallen rubble). Based on these observations, an airborne release fraction of 0.01 is selected for application to falling powders released from contaminated equipment punctured by demolition operations.

For demolition of walls and floors, DOE's factors for impaction stress due to vibration shock were selected as the most representative release fractions for the crushing processes; the factor selected was 0.001 for removable contaminants (DOE 1994). EPA's (EPA 1995) compilation of airborne release fractions includes a range of uncontrolled release fractions for crushing of ores and rocks that range from 0.012 to 6 pounds per ton of ore, which relates to an ARF of 6×10^{-6} to 3×10^{-3} —these ranges overlap, supporting the selection of the DOE values.

Load-out activities include picking up rubble with either a front-end loader or thumb and bucket on the excavator and dumping of rubble and larger pieces into transfer containers. Similar activities may also occur at a sorting/sizing station. As the material falls into the container from the elevated bucket of the loader where it originates, it will be subject to entrainment in the air. EPA considers its emission factor equation for aggregate-handling and storage piles to be applicable to the drop of bulk material onto piles (adapted from EPA 1995; available at <http://www.epa.gov/ttn/chief/ap42/>):

$$\text{ARF}_{\text{DROP}} = 1.6 \times 10^{-6} [(WS/2.2)^{1.3}] / [(M/2)^{1.4}] \quad (4.3)$$

where WS = characteristic wind speed over drop of material (m/s)—A characteristic wind speed for rubble drop was calculated using a characteristic wind speed for the site estimated by examining a wind climatology from the Hanford Site (Mantooth 2003). A compilation of average wind speeds was provided in the climatology. The ARF is more influenced by periods of higher winds (such as wind

gusts). The characteristic wind speed for rubble-handling was estimated to be 3.2 m/s (AphaTRAC 2003a); the result is not sensitive to this assumption.

M = moisture value associated with dry material (control effectiveness of water spray handled separately) (%). Because water spray and mist are applied to the pile, a moisture value of 2% for a wet construction aggregate was chosen, based on past experience. Small changes in assumed moisture content result in large variation of the resulting ARF, and the ARF decreases more than exponentially with M; the 2% value selected is believed to be conservatively low, resulting in a calculated ARF that should overestimate the releases via this route.

The EPA equation includes a particle-size multiplier ranging from about 0.1 to 0.8. For this analysis, this was conservatively set to 1.0 for all particle sizes. Using these values, the ARF for rubble-handling is estimated to be 2.3×10^{-6} .

4.1.4 Respirable Fraction

The RF is the fraction of airborne radionuclides as particles that can be transported through air and inhaled into the human respiratory system. The RF is assumed to include particles 10- μ m AED and less. In this study, all of the suspendable material is addressed (not just the respirable portion). It is estimated that most radioactive particles in the contamination are respirable in size. In this study, the radioactive particles are considered to be all 5 microns. This particle size is an AERMOD input parameter that is used for transport and deposition computations.

A respirable fraction of 1.0 is applied in the ST equation because the removal of nonrespirable particles from the plume is treated separately as a transport and dispersion function within the AERMOD modeling.

4.1.5 Leak-Path Factor

The LPF is the fraction of the radionuclides in the aerosol transported through some confinement deposition or filtration mechanism. For the purpose of this study, the LPF is used to address any controls applied during and after the demolition process. This includes the effects of water mists, sprays, and fixatives applied to surfaces and rubble after demolition.

The application of a water mist to contaminated surfaces during demolition serves to reduce the percentage of airborne particulates in the respirable size range. The efficiency of the mist varies with each application and depends on, among other variables, mist particle size, water flow rate, and the size of potential airborne particles. For the purpose of this analysis, the water-mist application is assumed to reduce the quantity of airborne particulates by 90%. The efficiency of the water-mist process must be weighed in light of the generated waste stream and the need to confine and capture runoff from the misting process. Thus, the LPF for concrete crushing is assumed to be 0.1. This value is slightly lower than that used for the 233-S Building (0.3), based on observations of the effectiveness of the misting on that facility^(a) and during demolition of 232-Z.

(a) Conversation with Dan Mantooth, 26 May 2004. A continuous application of water from an atomizer (e.g., a “fog cannon”) is assumed.

4.1.6 Limitation of Airborne Contamination

The dosimetry depends on the mixture of radioisotopes present. The inventory listed in Table 3.1 is assumed to represent the UO_3 present in the 224-U and 224-UA buildings and equipment. The spectrum of radionuclides is assumed to be constant.

DOE (1998) regulations specify in 10 CFR 835.2, "Definitions," that an airborne radioactivity area means any area accessible to individuals where the concentration of airborne radioactivity above natural background exceeds or is likely to exceed the DAC, or an individual present in the area without respiratory protection could receive an intake exceeding 12 DAC-hours in a week. If radionuclides "A," "B," and "C" are present in concentrations C_A , C_B , and C_C , and if the applicable DACs are DAC_A , DAC_B , and DAC_C , respectively, then the concentrations shall be limited so that the following relationship exists:

$$\frac{C_A}{\text{DAC}_A} + \frac{C_B}{\text{DAC}_B} + \frac{C_C}{\text{DAC}_C} \leq 1 \quad (4.4)$$

For a mixture of radionuclides where the concentrations of each are expressed in terms of a fraction, f , of a total, DAC_T , this can be written as:

$$\frac{f_A * \text{DAC}_T}{\text{DAC}_A} + \frac{f_B * \text{DAC}_T}{\text{DAC}_B} + \frac{f_C * \text{DAC}_T}{\text{DAC}_C} \leq 1 \quad (4.5)$$

This relationship can be used to determine a maximum total concentration that meets the requirements as:

$$\frac{f_A}{\text{DAC}_A} + \frac{f_B}{\text{DAC}_B} + \frac{f_C}{\text{DAC}_C} = \frac{1}{\text{DAC}_T} \quad (4.6)$$

This sum-of-fractions approach has been used to determine a compound DAC for the mixture in the UO_3 complex using the individual radionuclide DACs listed in the Appendix of 10 CFR 835. Using all of the reported radionuclides in the inventory, the DAC is $5.34 \times 10^{-10} \mu\text{Ci/mL}$.

The 20 dpm/100 cm^2 alpha-emitter limit is equivalent to 1.03×10^{-3} grams/ m^2 ; a 100 dpm/100 cm^2 alpha-emitter limit is equivalent to 0.0513 g/ m^2 ."

4.2 Unit Operations/Release Mechanisms

ST release rates have been estimated for seven unit operations:

- Demolition of building segments with an excavator/multiprocessor
- Load-out of building segment rubble with a front-end loader
- Demolition of calciners and equipment with multiprocessor
- Pick-up of calciners and equipment segment rubble with front-end loader and excavator
- Demolition of ducting, cyclones, and filter housings with multiprocessor
- Pick-up of ducting, cyclones, and filter housings with front-end loader and excavator
- Resuspension during off-shift periods.

A summary of the various parameters and their application in the source-term equation is provided in Table 4.1.

4.3 Estimated Release Rates

A series of spreadsheets were prepared to implement the models described above for the release rates for unit operations that define the steps of the demolition. The atmospheric transport analysis applied these on the appropriate number of days to complete the full demolition. These results are provided as the spreadsheet output listings presented in Appendix A.

The listings in Appendix A provide the results for unit operations demolishing external dust-handling equipment (ducts, cyclones, filter housings), buildings, calciners and associated equipment, and load-out of rubble from each in the immediate vicinity of the excavation.

The total emissions over the entire demolition procedure are also presented in the spreadsheet in Appendix A. It is interesting to note that the total amount of contaminated, respirable dust generated over the entire operation is dominated by about 20 grams from the dust-handling equipment of each building. These releases will occur over a brief period (less than one working day per building). The external filter housings dominate the source term and the releases; the emissions during the removal of these components will dominate the entire deposition footprint of the whole activity.

5.0 Atmospheric Dispersion and Deposition Modeling

Releases of contaminants to the air during the demolition activities described above potentially can have impacts in terms of the resulting increases in air and soil concentrations. An atmospheric dispersion modeling analysis has been conducted to generate estimates of these concentrations.

Potential air and soil exposures are modeled for the proposed demolition of the 224-U and 224-UA Buildings using the air dispersion model, AERMOD. AERMOD was developed by EPA and is the recommended dispersion model for regulatory air-quality computations. AERMOD includes formulations for addressing air dispersion in the immediate vicinity of air-emission sources. The model has dry deposition algorithms that account for the particle-size distribution and density as well as local surface and meteorological conditions. Important in the selection of AERMOD for this application is its capability to address building wake effects; the current version of AERMOD incorporates the building wake formulations developed by EPRI. The most recently released version of AERMOD (Version 07026 as implemented in Lakes^a ISC/AERMOD Version: 5.9.0) was used.

AERMOD information and documentation is available at EPA's website for regulatory air models (EPA 2008). AERMOD is considered a commercial model. For Hanford Site applications, such a model must be tested to verify that it is operating correctly in its current implementation (Project Hanford Management System 2002). A series of test cases distributed with AERMOD obtained from the EPA website (EPA 2008) were run before and after the computations reported here. The AERMOD runs were conducted using two computers (PNNL property numbers WE13827 and WE13623) with the Windows XP operating system with recent updates installed on both computers. Test case results which are documented in the project files shows the code to be working correctly before and after the production runs.

5.1 Air-Dispersion Modeling Assumptions and Data

AERMOD is used to model the air concentrations and soil deposition associated with the planned demolition activities for 224-U and 224-UA Buildings

5.1.1 Meteorological Data

The air-dispersion analysis used multiple years of local meteorological data to define the local dispersion climatology. Five years of meteorological data records (calendar years 2002 to 2006) were obtained from the Hanford Meteorological Station (HMS) database for the analysis.^(b) Surface meteorological input data to AERMOD consisted of a merged dataset containing surface data incorporating wind speed and direction data from the Hanford telemetry station number 19 located in the 200W area combined with meteorological surface observations from the central HMS station. Vertical

(b) Ken Burk, Hanford Meteorological Station, Email dated 12/13/2007 defining link for 1997 to 2006 for Hanford meteorological data.

structure input data to AERMOD consisted of radiosonde data from the meteorological station at the Spokane airport.^(a)

Figure 5.1 shows a wind rose plot^(b) for all hours for the 5 years from Hanford Station #19. Figure 5.2 and Figure 5.3 show wind rose plots^(a) for the months and hours that the demolition activities are planned. A description of the Hanford observation network along with an annual summary of the local climatology can be found in Hoitink et al. (2004).

5.1.2 Source Characteristics

The main sources for air emissions will be the removal of the bag houses. These bag houses were modeled as a matrix of point sources, with each bag structure modeled as three vertical points (top, middle, and near ground level). The AERMOD runs were configured to directly produce maximum hourly concentration and deposition values for the days associated with the demolition activities.

5.1.3 Modeling Approach

The demolition is planned to occur in either the July to September or the October to December time frames. To fully bracket the possible peak exposures when the demolition occurs, the peak values of air and soil concentrations were modeled for an entire year of meteorological observations.

The activities are to occur during the day shift. The worst case for the occurrence of the highest air concentrations is for the majority of the release to occur over a short time period. To evaluate the potential exposure levels from the planned demolition activities, the local patterns of potential peak air concentrations and soil deposition were computed as though the estimated release from each of the buildings occurred during 1 hour. By looking at the potential peaks for all the hours during the planned

work periods, the worst-case values are defined. The two proposed 3-month time periods for the demolition activities are included in this annual bounding computation.

5.1.4 Receptor Grids

Initial computations were made for a rectangular grid appropriate for defining the spatial patterns of the locations of the maximum air concentrations and deposition amounts.

5.2 Air-Dispersion Modeling Results

The air-dispersion results are presented as maps of potential peak air concentrations and deposition amounts. All demolition emissions were conservatively assumed to occur in 1 hour during the removal of the bag house structures. The maps are prepared as a composite of the peak values that were modeled for each hour over a five-year period. The results thus include the planned work periods but provide bounding information based on conditions that occur over at any time of the year. The values at each point on these maps represent the worst exposure that could occur at that point during demolition—no matter what time of year is selected for the demolition activities. The actual exposures that will occur during demolition will be defined by the ambient meteorological conditions that occur during the actual demolition process. The results of the modeling bound the values for the actual exposures.

The 224-U building demolition will occur first. Figure 5.4 is a map of the predicted peak hourly air concentrations for the 224-U building demolition. On this and following plots of air concentrations, isopleths are plotted at intervals to indicate conformance to the DAC-hour exposure limit given above; areas within the “ $341 \mu\text{g}/\text{m}^3$ ” isopleth have all predicted peak air exposures under that limit. Figure 5.5 is a map of the predicted peak deposition amounts for the 224-U building demolition. On this and following plots of deposition, isopleths are plotted at intervals to indicate conformance to the $1000 \text{ dpm}/100 \text{ cm}^2$ exposure limit given above; areas within the “ $0.05 \mu\text{g}/\text{m}^2$ ” isopleth have all predicted peak soil uranium depositions under the limit.

After the 224-U Building is removed, the demolition of 224-UA will start. The air-dispersion modeling accounts for the fact that the 224-U Building is gone. Figure 5.6 is a map of the predicted peak hourly air concentrations for the 224-UA Building demolition. Figure 5.7 is a map of the predicted peak deposition amounts for the 224-UA Building demolition by itself, and Figure 5.8 is a map of the predicted peak deposition amounts for both the 224-UA and 224-UA Building demolitions.

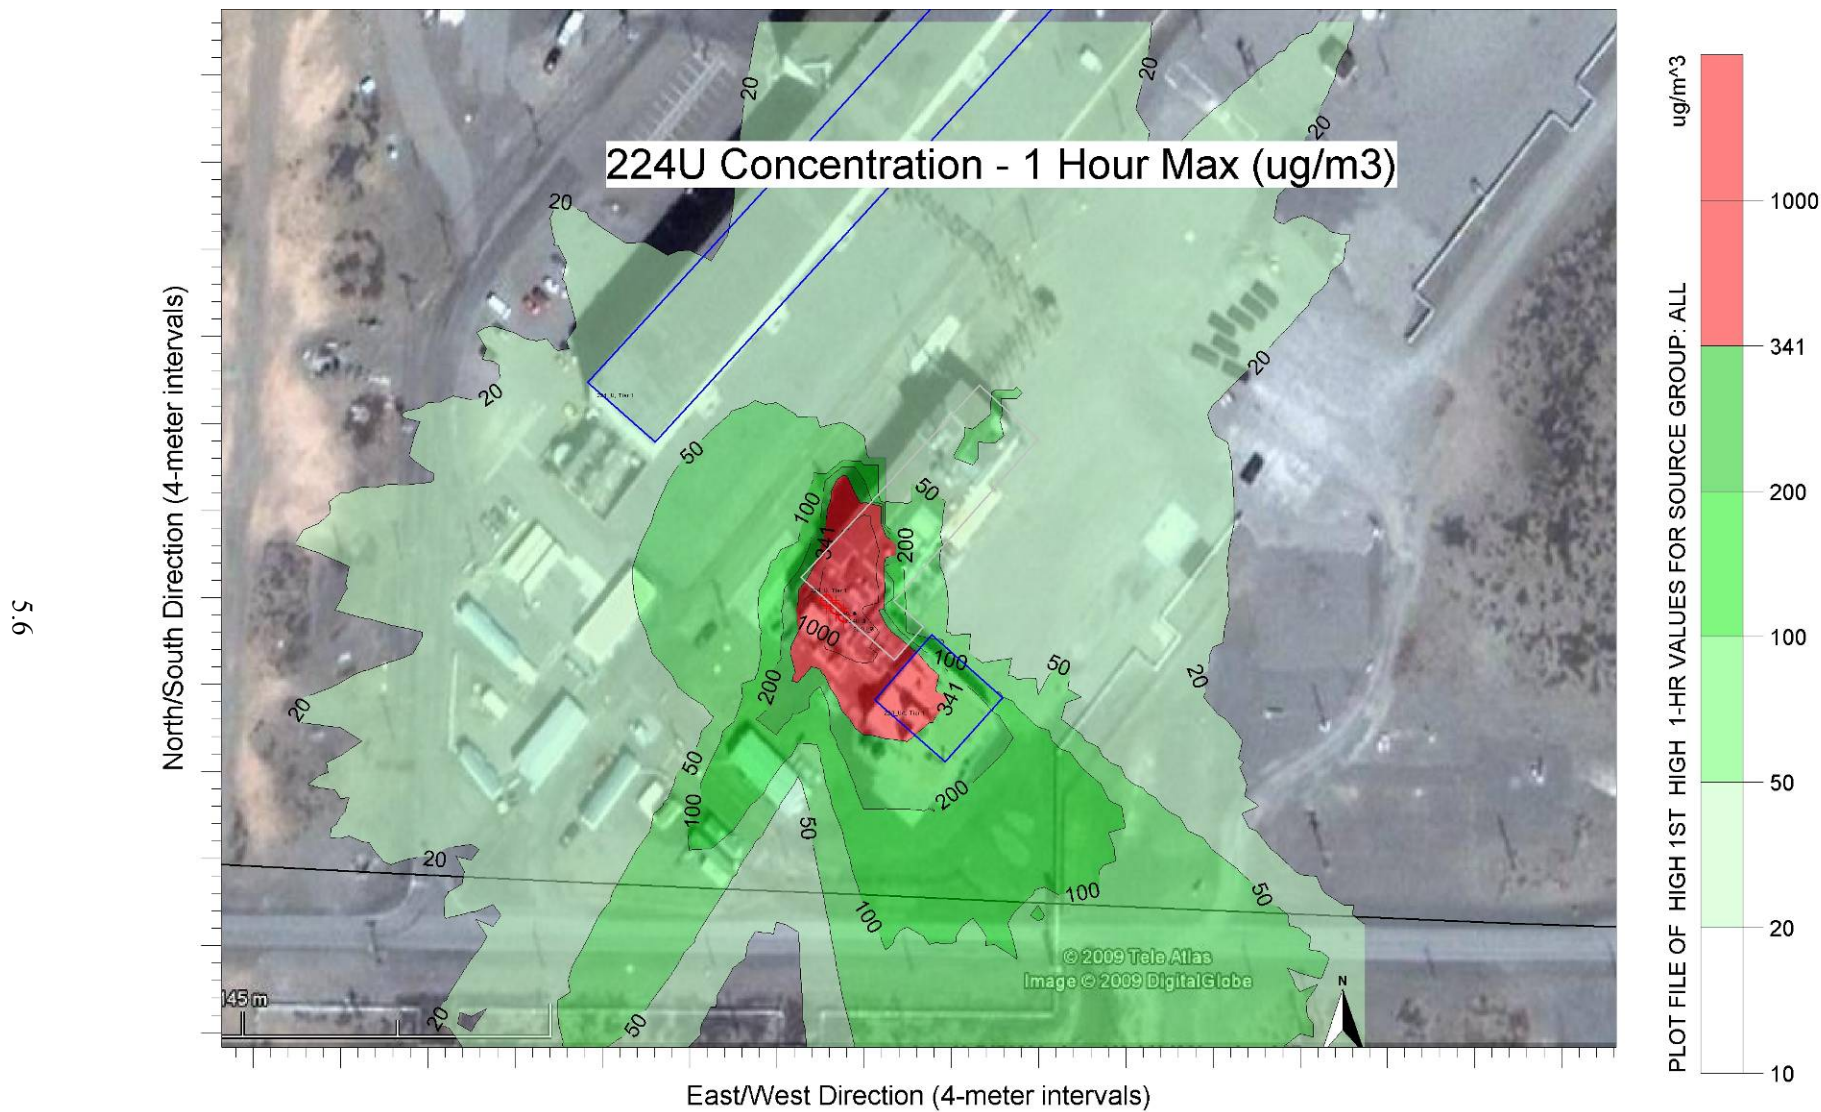

Figure 5.4. Predicted Peak Hourly Air Concentrations for the 224-U Building Demolition; Values Less Than 341 $\mu\text{g}/\text{m}^3$ Correspond to Concentrations Below 12 DAC-hrs

Figure 5.5. Predicted Peak Deposition Amounts for the 224-U Building Demolition; Values Less Than 0.05 $\mu\text{g}/\text{m}^2$ Correspond to Uranium Deposition Rates of Less Than 1000 dpm/100 cm^2

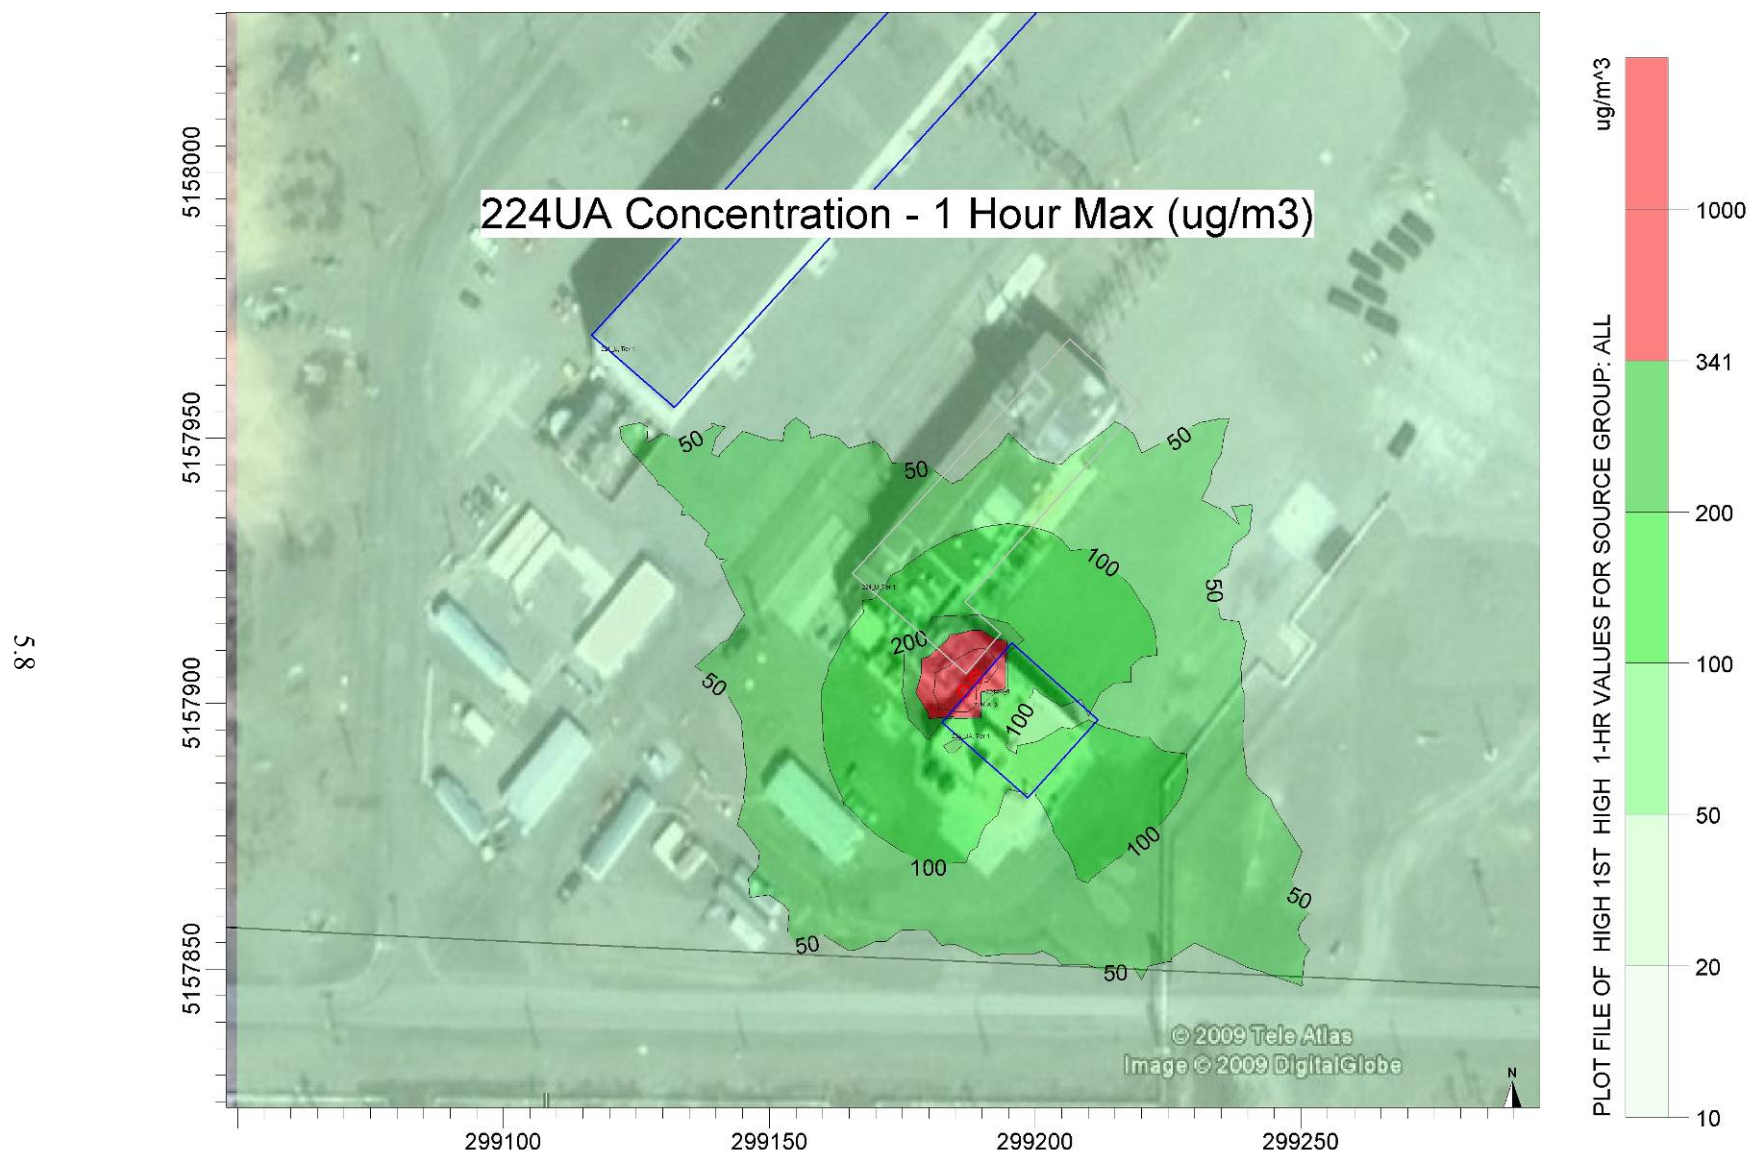

Figure 5.6. Predicted Peak Hourly Air Concentrations for the 224-UA Building Demolition; Values Less Than 341 $\mu\text{g}/\text{m}^3$ Correspond to Concentrations Below 12 DAC-hrs

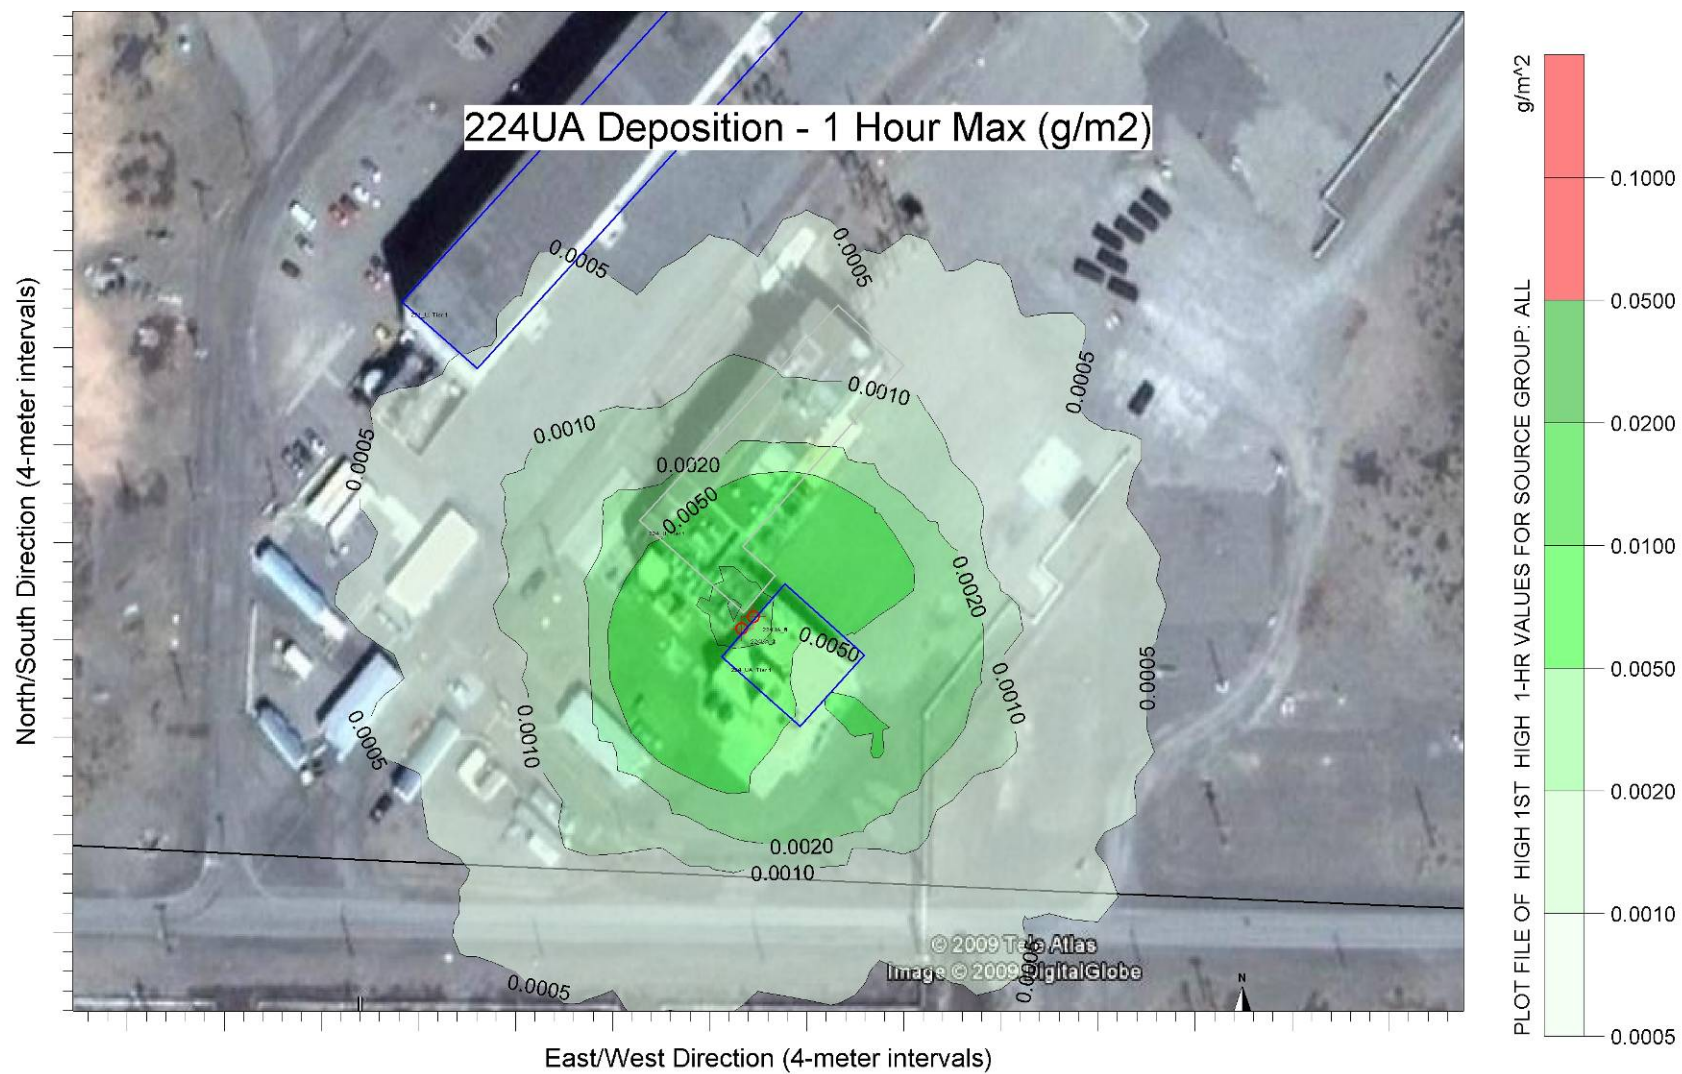

Figure 5.7. Predicted Peak Deposition Amounts for the 224-UA Building Demolition; Values Less Than 0.05 $\mu\text{g}/\text{m}^2$ Correspond to uranium Deposition Rates of Less Than 1000 dpm/100 cm^2

Appendix B

AERMOD Emission Rates

Appendix B

AERMOD Emission Rates

Emission rates for input to the AERMOD model were computed for the demolition of the two sets of filter bags by assuming that the estimated mass suspended by demolition given in Appendix A occurred in a one hour period. The release from each filter bag was modeled as three points of release located from the surface up to the height of the filter structure. The suspended mass was assumed to be equally distributed over the each of the matrix of assumed release points. Emission rates used in the modeling for the 224-U and 224-UA buildings and associated structures listed in the table below are computed by dividing the estimated suspended mass by the number of modeled release points and the number of seconds in an hour (i.e., 3600 seconds).

Computation of AERMOD Emission Rate Inputs

Source Name	Number of Release Points	Max. Mass Suspended In One Hour (g)	Source Id	Release Time (s)	AERMOD Emission Rate (g/s)	Release Height (m)

***      MODEL SETUP OPTIONS SUMMARY      ***
- - - - -

**Model Is Setup For Calculation of Average CONCentration Values.
**Model Is Setup For Calculation of Dry DEPosition Values.

-- DEPOSITION LOGIC --
**Model Uses DRY DEPLETION.  DDPLETE = T
**Model Uses WET DEPLETION.  WDPLETE = T
```

**NO GAS DRY DEPOSITION Data Provided.

**Model Uses RURAL Dispersion Only.

**Model Uses User-Specified Options:

1. Stack-tip Downwash.
2. Model Assumes Receptors on FLAT Terrain.

**Other Options Specified:

TOXICS - Allows use of TOXICS option enhancements.

**Model Assumes No FLAGPOLE Receptor Heights.

**Model Calculates 1 Short Term Average(s) of: 1-HR

**This Run Includes: 15 Source(s); 1 Source Group(s); and 2500 Receptor(s)

**The Model Assumes A Pollutant Type of: UO3

**Model Set To Continue RUNning After the Setup Testing.

**Output Options Selected:

Model Outputs Tables of Highest Short Term Values by Receptor (RECTABLE Keyword)

Model Outputs External File(s) of High Values for Plotting (PLOTFILE Keyword)

**NOTE: The Following Flags May Appear Following CONC Values: c for Calm Hours
m for Missing Hours
b for Both Calm and Missing Hours

**Misc. Inputs: Base Elev. for Pot. Temp. Profile (m MSL) = 0.00 ; Decay Coef. = 0.000 ; Rot. Angle = 0.0
Emission Units = GRAMS/SEC ; Emission Rate Unit Factor = 0.10000E+07
Output Units = MICROGRAMS/M**3

**Approximate Storage Requirements of Model = 1.5 MB of RAM.
