Completeness of Testing

This report describes the results of work and testing specified by test plan TP-WTPSP-032. The work and any associated testing followed the quality assurance requirements outlined in the test plan. The descriptions provided in this test report are an accurate account of both the conduct of the work and the data collected. Test plan results are reported. Also reported are any unusual or anomalous occurrences that are different from expected results. The test results and this report have been reviewed and verified.

Summary

This document reports on a series of tests conducted to assess the proposed air sampling locations for the Hanford Tank Waste Treatment and Immobilization Plant (WTP) Group 3-4 exhaust stacks with respect to the applicable criteria regarding the placement of an air sampling probe. The HV-S1, HV-S2, and IHLW-S1 exhaust stacks were tested together as a group (Test Group 3-4) because they share a geometric attribute: the common factor in their design is that the last significant flow disturbance upstream of the air sampling probe is a jog (i.e., two conjoined bends of equal and opposite curvature resulting in a change in elevation of the duct). Federal regulations[1] require that a sampling probe be located in the exhaust stack according to criteria established by the American National Standards Institute/Health Physics Society (ANSI/HPS) N13.1-1999, *Sampling and Monitoring Releases of Airborne Radioactive Substances from the Stack and Ducts of Nuclear Facilities*. These criteria address the capability of the sampling probe to extract a sample that represents the effluent stream.

The testing on scale models of the stacks conducted for this project was part of the River Protection Project—Waste Treatment Plant Support Program under Contract No. DE-AC05-76RL01830 according to the statement of work issued by Bechtel National, Inc. (BNI, 24590-QL-SRA-W000-00101, *N13.1-1999 Stack Monitor Scale Model Testing and Qualification*, Revision 1, 9/12/2007) and Work Authorization 09 of Memorandum of Agreement 24590-QL-HC9-WA49-00001. The internal Pacific Northwest National Laboratory (PNNL) project for this task is 53024, *Work for Hanford Contractors Stack Monitoring*. The testing described in this document was further guided by the Test Plan *Air Sampling Probe Location Tests for Waste Treatment Plant HV-S1, HV-S2 and IHLW-S1 (Group 3-4) Air Exhaust Systems* (TP-WTPSP-032).

The tests conducted by PNNL during 2012 on the Group 3-4 scale model systems are described in this report. The series of tests consists of various measurements taken over a grid of points in the duct cross section at the designed sampling probe locations. The ANSI/HPS N13.1-1999 qualification criteria concern the following properties of the air flowing through the ducts where the air sampling probes are to be located:

1. Uniform Air Velocity—The gas momentum across the stack cross section where the sample is extracted should be well mixed or uniform. The uniformity is expressed as the variability of the measurements about the mean, expressed as the percent coefficient of variance (%COV). It is calculated as the standard deviation divided by the mean and expressed as a percentage—the lower the %COV value, the more uniform the velocity.
2. Angular Flow—The purpose of this test is to determine whether the air velocity vector is aligned with the sampling nozzle.
3. Uniform Concentration of Tracer Gases—A uniform contaminant concentration in the sampling plane enables the extraction of samples that represent the true concentration.

[1] Title 40 of the Code of Federal Regulations (CFR), Part 61, National Emissions Standards for Hazardous Air Pollutants (NESHAP), Subpart H, *National Emission Standard For Emissions of Radionuclides other than Radon from Department of Energy Facilities*.

4. Uniform Concentration of Tracer Particles—Uniformity in contaminant concentration at the sampling probe was further demonstrated using tracer particles large enough to exhibit inertial effects. Particles of 10-µm aerodynamic diameter were used.

The scale model test results for the proposed sampling probe locations are summarized below.

Table S.1. Summary of Preferred Sampling Probe Location Results for the Group 3-4 Scale Model Stacks

	Acceptance Criteria	Units	HV-S1	HV-S2	IHLW-S1
Velocity Uniformity	≤20	%COV	2.8 – 6.6	2.5 – 7.8	4.2 – 10
Flow Angle	≤20	Degrees	3.1 – 4.7	3.9 – 12.5	1.3 – 9.3
Gas Tracer Uniformity	≤20	%COV	1.1 – 4.7	1.8 – 7.2	0.9 – 5.8
	≤30	Maximum % Deviation from Mean	2.6 – 7.9	4.3 – 14.2	1.8 – 11.2
Particle Tracer Uniformity	≤20	Normalized %COV	4.4 – 11.7	5.3 – 13	3.3 – 15.2

For the HV-S1 and HV-S2 stacks alternate test ports also showed satisfactory results and make allowance for limited construction variance in the probe locations.

Based on these scale model tests, the locations proposed for the air sampling probes in each of the three Group 3-4 stacks meet the requirements of the ANSI/HPS N13.1-1999 standard. Additional velocity uniformity and flow angle tests on the actual stacks will be necessary during cold-startup to confirm the validity of the scale model results in representing the actual stacks. In particular, the velocity uniformity test results for the actual stacks must be within 5%COV of the range of results listed for the scale model so that scale model results can be said to be representative of the stack. If the velocity uniformity results on the actual stack fall within these bounds and flow angle test results fall within qualification criteria (mean angle $\leq 20^{o}$), the scale model results may be used as a substitute for the actual stack.

Quality Assurance

The PNNL quality assurance (QA) program is based on the requirements defined in the U.S. Department of Energy Order 414.1D, *Quality Assurance,* and 10 CFR 830, *Energy/Nuclear Safety Management*, and Subpart A—*Quality Assurance Requirements* (a.k.a., the Quality Rule). PNNL has chosen to implement the following consensus standards in a graded approach:

- ASME NQA-1-2000, *Quality Assurance Requirements for Nuclear Facility Applications*, Part I, "Requirements for Quality Assurance Programs for Nuclear Facilities".
- ASME NQA-1-2000, Part II, Subpart 2.7, *Quality Assurance Requirements for Computer Software for Nuclear Facility Applications*.
- ASME NQA-1-2000, Part IV, Subpart 4.2, *Graded Approach Application of Quality Assurance Requirements for Research and Development*.

The procedures necessary to implement the requirements are documented through PNNL's "How Do I…?" (HDI), which is a system for managing the delivery of laboratory-level policies, requirements, and procedures.

The Waste Treatment Plant Support Program (WTPSP) implements an NQA-1-2000 QA program, using a graded approach presented in NQA-1-2000, Part IV, Subpart 4.2. The WTPSP Quality Assurance manual (QA-WTPSP-002) describes the technology life cycle stages under the WTPSP QA plan (QA-WTPSP-0001). The technology life cycle includes the progression of technology development, commercialization, and retirement in process phases of basic and applied research and development (R&D), engineering and production, and operation until process completion. The life cycle is characterized by flexible and informal QA activities in basic research, which becomes more structured and formalized through the applied R&D stages. The work described in this report has been completed under the QA Technology level of Developmental Work as the data will be used for applying air discharge permits. Developmental Work is described below:

- DEVELOPMENTAL WORK—Developmental work consists of research tasks moving toward technology commercialization. These tasks still require a degree of flexibility, and there is still a degree of uncertainty that exists in many cases. The role of quality on development work is to make sure that adequate controls exist to support movement into commercialization.

WTPSP addresses internal verification and validation activities by conducting an Independent Technical Review of the final data report in accordance with WTPSP's procedure QA-WTPSP-601, *Document Preparation and Change*. This review verifies that the reported results are traceable, that inferences and conclusions are soundly based, and the reported work satisfies the test plan objectives. Appendix E lists the reviewed test plan, test instructions, and calculation packages used for the tests documented in this report.

Acknowledgments

Preparing, executing, and post-processing these scale model measurements involved a number of Pacific Northwest National Laboratory staff. We would like to particularly acknowledge the support of our quality engineer, Kirsten Meier, and the administrative support from Andrea Boehler, Chrissy Charron, and Mona Champion. We would also like to express our appreciation to scientific staff members Carmen Arimescu, Yin-Fong Su, and Xiao-Ying Yu who conducted measurements under a variety of weather conditions. Additionally, Matthew Barnett, Carmen Arimescu, Rosanne Aaberg, Elizabeth Golovich, and Susan Sande provided technical reviews. Cary Counts and Megan Peters provided editorial support for this report.

Funding for this effort was provided by the Department of Energy's Waste Treatment and Immobilization Plant Project through a subcontract with Bechtel National, Inc. Pacific Northwest National Laboratory is operated for the U.S. Department of Energy by Battelle under Contract DE-AC05-76RL01830.

1.0 Introduction

The purpose of this series of scale model tests is to document the extent to which the current Bechtel National, Inc. (BNI) designs for the HV-S1, HV-S2, and IHLW-S1 air exhaust stacks in the Hanford Tank Waste Treatment and Immobilization Plant (WTP) meet the applicable regulatory criteria governing effluent monitoring systems. The emissions from these high-level waste facility air exhaust stacks may exceed the 0.1-millirem per year threshold limit given in Title 40 of the Code of Federal Regulations (CFR), Part 61, National Emissions Standards for Hazardous Air Pollutants (NESHAP), Subpart H, *National Emission Standard For Emissions of Radionuclides other than Radon from Department of Energy Facilities*. The NESHAP rule requires that a sampling probe be located in the exhaust stack according to criteria established by the American National Standards Institute/Health Physics Society (ANSI/HPS) N13.1-1999, *Sampling and Monitoring Releases of Airborne Radioactive Substances from the Stack and Ducts of Nuclear Facilities*.[1] The capability of the sampling probe locations to meet this standard has been demonstrated with a series of tests on scale models. These data will be used by BNI as input to the air discharge permitting process. These three stacks were tested together as a group (Test Group 3-4) because they share a geometric attribute: the common factor in their design is that the last significant flow disturbance upstream of the air sampling probe is a jog (i.e., two conjoined bends of equal and opposite curvature resulting in a change in elevation of the duct).

This work is performed as part of the River Protection Project—Waste Treatment Plant Support Program under Contract No. DE-AC05-76RL01830 according to the statement of work issued by BNI, 24590-QL-SRA-W000-00101, N13.1-1999 Stack Monitor Scale Model Testing and Qualification, Revision 1, 09/12/2007 and Work Authorization 09 of Memorandum of Agreement 24590-QL-HC9-WA49-00001. The internal Pacific Northwest National Laboratory (PNNL) project for this task is 53024, *Work for Hanford Contractors Stack Monitoring*.

PNNL personnel conducted scale model tests during 2012. No BNI personnel were directly involved in the tests. The BNI WTP point of contact and facility engineers provided the most current engineering input to support PNNL's tests. BNI retains responsibility for the technical design of the stack discharge and air monitoring systems.

1.1 Qualification Criteria

The qualification criteria for the location of a stack air monitoring probe are taken from ANSI/HPS N13.1-1999, section 5.2.2 and are paraphrased as follows:

1. Uniform Air Velocity—It is important that the gas velocity be fairly uniform across the stack cross section where the sample is extracted. Consequently, the velocity is measured at several discrete points in the duct cross section at the proposed location of the sampling nozzle. The uniformity is expressed as the variability of the measurements about the mean. This is expressed using the percent coefficient of variation (%COV),[2] which is the standard deviation divided by the mean and expressed as a percentage—the lower the %COV value, the more uniform the velocity. The qualification

[1] Health Physics Society, McLean, Virginia. The standard has been reaffirmed in 2011 and is identical to the 1999 version. The regulations have not been updated yet, so the 1999 version is still referenced.

[2] *Coefficient of variation* is considered "dated" terminology. The modern terminology is *percent relative standard deviation*. However, because the standard uses the older terminology, it will likewise be used here.

criterion is that the %COV of the air velocity must be ≤20% in the center two-thirds of the duct cross section where the sampling probe is to be located.

2. Angular Flow—Sampling nozzles are typically aligned with the axis of the stack. If the air travels through the stack in cyclonic fashion, the air velocity vector approaching a sampling nozzle could be sufficiently misaligned with the nozzle to impair extraction of particles. Consequently, the flow angle is measured in the duct at the proposed location of the sampling probe. The average of the flow angle measurements (made at the same grid of points as the velocity measurements) should not exceed 20° relative to the sampling nozzle axis.
3. Uniform Concentration of Tracer Gases—A uniform contaminant concentration in the sampling plane enables the extraction of samples that represent the true concentration within the duct. The uniformity of the concentration is first tested with a tracer gas to represent gaseous effluents. The fan is a good mixer, so injecting the tracer downstream of the fan provides worst-case results. The qualification criteria are that 1) the %COV of the measured tracer gas concentration is ≤20% across the center two-thirds of the duct cross section at the sampling location, and 2) the concentrations at all the measurement points cannot deviate from the mean by >30%.
4. Uniform Concentration of Tracer Particles—The second set of tests addressing contaminant concentration uniformity at the sampling position uses tracer particles large enough to exhibit inertial effects. Tracer particles of 10-μm aerodynamic diameter (AD) are used by default unless it is known that larger contaminant particles will be present in the airstream. The qualification criterion is that the %COV of particle concentration is ≤20% across the center two-thirds of the duct at sampling location.

Tests to determine if Criteria 1 through 4 were met were conducted on the three scale models of the Group 3-4 stacks (HV-S1, HV-S2, and IHLW-S1) at the proposed sampling location along the exhaust duct. By conducting tests on scale models of the exhaust systems, the designed air sampling locations can be qualified before cold commissioning, and compensatory measures could be made in the design if testing results were not satisfactory. All of the tracer concentration, velocity, and flow angle measurements were made using the same grid of points in a given cross section of the duct. The ANSI/HPS N13.1-1999 standard sets additional qualification criteria for the use of a scale model as a substitute for the actual stack.

- The scale model and its sampling location must be geometrically similar to the actual stack.
- The product of the hydraulic diameter and the mean velocity (DV) for the scale model must be within a factor of six of the DV for the actual stack.
- The Reynolds number for the actual and model stacks must be >10,000.
- The scale model results are considered valid if it is further shown that:
  - The velocity profile in the actual stack meets the uniformity criterion (%COV ≤20%).
  - The velocity uniformity COV values for the actual and model stacks agree within 5%COV.
  - The flow angle criterion (with a mean value less than or equal to 20°) is met.

The tests to determine the validity of the scale model testing will be performed during cold startup testing on the actual WTP stacks under separate test plans. The scale model testing conducted, as well as the results of these tests, is described in subsequent sections of this report.

2.0 Group 3-4 Stacks

2.1 Stack Geometry

Group 3-4 consists of three different stacks: HV-S1, HV-S2, and IHLW-S1. These three stacks were tested together as a group (Test Group 3-4) because they share a geometric attribute in their design in that the last significant flow disturbance upstream of the air sampling probe is a jog (i.e., two conjoined bends of equal and opposite curvature resulting in a change in elevation of the duct).

In these three stacks, the designed sampling probes will be located in horizontal sections of duct. Figure 2.1 through Figure 2.3 show the layout for each of the three stack designs, from the fan outlet to the base of the vertical duct. Figure 2.4 through Figure 2.6 show the scale model layout for each of the three stack designs. The simplified models are based on assumptions about the necessary simulation detail. These assumptions are listed below.

- Geometric simulation of the components upstream of the backdraft damper was ignored. Backdraft damper blades do not usually open fully. The partially open blades direct the air velocity vector toward one side of the duct resulting in considerable disruption to the air flow. Consequently, it was assumed that the air velocity and tracer uniformity downstream of the dampers would not be greatly influenced by equipment upstream of the dampers. This assumption has not been tested; however, this assumption had the benefit of reducing the cost of the models by using a single fan/filter/heater arrangement and the elimination of the control damper.

Components several duct diameters downstream of the sampling point are not modeled. It was assumed that the only effect of any components downstream of the sampling probe location would be to slightly change the pressure at the sampling port. While this assumption was not tested, components generally do not influence flow patterns upstream. Figure 2.7. through Figure 2.9 show photos of the scale models for each of the three stack designs.

The same fans were used for each of the three scale models. The fans were connected to a flexible duct that was connected to the backdraft damper. The backdraft damper was subsequently connected to each of the scale models for testing.

For each of the scale model stacks, Test Port 2 represents the planned location for operational stack sampling according to the current WTP BNI designs. The distance from the end of the duct jog to the center of Test Port 2 was approximately 20, 20, and 8 duct diameters for the HV-S1, IHLW-S1, and HV-S2 models, respectively. On the HV-S1 and IHLW-S1 systems, Test Port 1 is located approximately five duct diameters downstream of Test Port 2 to allow some flexibility in testing. For the HV-S2 system, Test Port 1 is located only two duct diameters downstream of Test Port 2.

The ratio of the prototype dimensions to the scale model dimensions varies with each system. Each scale model was constructed with a primary duct diameter of 12 in. for convenience and to maintain the ability to re-use the duct sections for subsequent stack designs. Table 2.1 lists the final diameter of the actual stack with the scaling factor for the 12-in. scale model diameter. The calculations of the key scale model dimensions were performed in spreadsheets and then verified and validated in accordance with appropriate quality assurance (QA) procedures. ANSI/HPS N13.1-1999 requires that the models be geometrically similar to the actual stacks. Acceptable deviations in key dimensions of the scale model

arising from scaling and fabrication errors are within about ±5% for cross-sectional dimensions and about 25% of a duct diameter in overall length between the sampling point and the flow disturbances. These deviations would have less impact on the test results than the normal standard deviation of repeat tests. The key scale model dimensions for the as-built scale models were measured and recorded by testing staff.

Table 2.1. Scaling Factor for 12-in.-Diameter Scale Model Stack

	Actual Diameter	Scaling Factor
HV-S1	60 in.	5.00
HV-S2	62 in.	5.17
IHLW-S1	34 in.	2.83

2.2 Stack Flows

Tests of scale model stacks were conducted at flow rates that bracket the range of expected normal and accident flow rates and operating configurations. Various combinations of flow rates and operating fans were tested. BNI provided normal, minimum, and maximum flow rates for each of the three systems tested in this group. Maximum flow rates are 125% of the normal flow rates, whereas minimum flow rates are 50% of normal.

Additional considerations come from the ANSI/HPS N13.1-1999 standard. The standard requires that the DV of the scale model be within a factor of six of the actual stack. For stacks with a circular cross section, this is equivalent to requiring that the ratio of flow rate to stack diameter be within a factor of six of the actual stack. The standard also requires that the Reynolds number for the prototype and model stacks must both exceed 10,000.

The WTP HV-S1 air exhaust system is equipped with two fans capable of 59,300 acfm (actual cubic feet per minute) flow each. The speed of both fans will be controlled with variable frequency drives to achieve the target flow rate. Only one fan will be operated at any given time, with the second fan in standby for use when maintenance needs arise on the primary fan. Each fan is equipped with an adjustable-speed drive to compensate for upstream filter loading and pressure variations.

There are two fans available to power the WTP HV-S2 exhaust system, which exhausts air from the C5 ventilation system of the high-level waste facility. One fan will be operated at a time, and one will be on standby. Each fan is capable of providing the maximum flow rate of 63,750 acfm, and is equipped with an adjustable-speed drive to compensate for filter loading and pressure variations.

Two fans are available to power the IHLW-S1 exhaust system of the high-level waste facility, which exhausts air from the C3 ventilation system. Only one fan will be operated at a time, and one will be on standby. Each fan is capable of providing the maximum flow rate of 13,100 acfm. Each fan is equipped with an adjustable-speed drive to compensate for filter loading and pressure variations.

Table 2.2 lists the flow conditions for the actual stack as well as the scale model stack. The flow rates provided by BNI were in acfm and were converted to standard flow rates to account for temperature (see Appendix D). The minimum air flow (in standard feet per minute [scfm]) and air velocity (in standard feet per minute [sfpm]) to achieve the assumed minimum and maximum actual stack flow are listed. The tabulated values of flow and velocity in the "Scale Model Minimum" columns are the minimum scaled values that will meet the criterion listed in Section 1.1 that the DV product be within a factor of six of the prototype. The scale model Reynolds numbers are calculated for those minima. One of the qualification criteria listed in Section 1.1 was that the Reynolds number for both the actual and scale model stack must be greater than 10,000. Therefore, the Reynolds number for the actual and scale model stacks at the minimum and maximum flow rates are included in Table 2.2. The conditions prescribed for these scale model tests fulfill the criterion of a Reynolds number greater than 10,000.

Table 2.2. Summary of Flow Parameters for Scale Model Stacks

	Air Flow (scfm)		Air Velocity (sfpm)		Reynolds Number	
Fan(s)–Flow	Actual Stack	Scale Model Minimum	Actual Stack	Scale Model Minimum	Actual Stack	Scale Model Minimum
HV-S1						
Single fan—max flow	55627	1854	2833	2361	1.5E+06	2.4E+05
Single fan –norm flow	45524	1517	2319	1932	1.2E+06	2.0E+05
Single fan—min flow	24202	807	1233	1027	6.3E+05	1.1E+05
HV-S2						
Single fan—max flow	53631	1730	2558	2203	1.4E+06	2.6E+05
Single fan –norm flow	48096	1551	2294	1976	1.2E+06	2.0E+05
Single fan—min flow	26040	840	1242	1070	6.6E+05	1.1E+05
IHLW-S1						
Single fan—max flow	11198	659	1776	839	5.2E+05	8.6E+04
Single fan –norm flow	9883	581	1567	740	4.6E+05	7.6E+04
Single fan—min flow	5351	315	849	401	2.5E+05	4.1E+04

Another qualification criterion listed in Section 1.1 pertains to the DV in the scale model relative to the stack. Table 2.3 lists the DV values for the stack as well as the DV values that are acceptable for the scale model. This minimum flow for the model is selected to be the lower boundary so the DV product is within a factor of six (i.e., one-sixth) of the DV product for the actual stack. Likewise, the maximum

flow for the model is selected to be the upper boundary so the DV product is within a factor of six (i.e., six times) of the DV product for the actual stack.

Table 2.3. Summary of DV Values for Scale Model Stacks

	DV		
	Predicted for Actual	Acceptable Range for Scale Model	
System	Stack	Minimum	Maximum
HV-S1	1.42E+04	2.36E+03	8.50E+04
HV-S2	1.32E+04	2.20E+03	7.93E+04
IHLW-S1	5.03E+03	8.39E+02	3.02E+04

3.0 Testing Methods

The testing methods were based on the requirements of ANSI/HPS N13.1-1999. A test plan, TP-WTPSP-032, *Air Sampling Probe Location Tests for Waste Treatment Plant HV-S1, HV-S2, and IHLW-S-1 (Group 3-4) Air Exhaust Systems*, was prepared by PNNL and approved by BNI. This plan referenced the use of PNNL procedures, which define how the test should be conducted in general. A test instruction (TI) was prepared for each test type and for each scale model stack. These TIs contain specific instructions pertaining to the tests that are not addressed in the general procedures. Such information includes the following:

- Layout of measurement points
- Location of tracer injection points
- List of equipment and instrumentation
- Safety requirements
- List of test runs
- Test description and measurement data sheets with hand entries
- Table of preliminary results.

Because the final data sheets and a description of the test methods are included in this report, the TIs are not included here. The QA program that is implemented for this project is described in Section 3.1 and a summary of the stack testing methods used for each of the four test types is presented in Section 3.2.

3.1 Quality Assurance

The PNNL QA program is based on the requirements defined in the U.S. Department of Energy Order 414.1D, *Quality Assurance,* and 10 CFR 830, *Energy/Nuclear Safety Management*, and Subpart A—*Quality Assurance Requirements* (a.k.a., the Quality Rule). PNNL has chosen to implement the following consensus standards in a graded approach:

- ASME NQA-1-2000, *Quality Assurance Requirements for Nuclear Facility Applications*, Part I, "Requirements for Quality Assurance Programs for Nuclear Facilities".
- ASME NQA-1-2000, Part II, Subpart 2.7, *Quality Assurance Requirements for Computer Software for Nuclear Facility Applications*.
- ASME NQA-1-2000, Part IV, Subpart 4.2, *Graded Approach Application of Quality Assurance Requirements for Research and Development*.

The procedures necessary to implement the requirements are documented through PNNL's "How Do I…?" (HDI), which is a system for managing the delivery of laboratory-level policies, requirements, and procedures.

The Waste Treatment Plant Support Program (WTPSP) implements an NQA-1-2000 QA program, using a graded approach presented in NQA-1-2000, Part IV, Subpart 4.2. The WTPSP Quality Assurance manual (QA-WTPSP-002) describes the technology life cycle stages under the WTPSP QA plan

(QA-WTPSP-0001). The technology life cycle includes the progression of technology development, commercialization, and retirement in process phases of basic and applied research and development (R&D), engineering and production, and operation until process completion. The life cycle is characterized by flexible and informal QA activities in basic research, which becomes more structured and formalized through the applied R&D stages. The work described in this report has been completed under the QA Technology level of Developmental Work as the data will be used for applying air discharge permits.

- DEVELOPMENTAL WORK—Developmental work consists of research tasks moving toward technology commercialization. These tasks still require a degree of flexibility, and there is still a degree of uncertainty that exists in many cases. The role of quality on Developmental Work is to make sure that adequate controls exist to support movement into commercialization.

WTPSP addresses internal verification and validation activities by conducting an Independent Technical Review of the final data report in accordance with WTPSP's procedure QA-WTPSP-601, *Document Preparation and Change*. This review verifies that the reported results are traceable, that inferences and conclusions are soundly based, and the reported work satisfies the test plan objectives. Appendix E lists the reviewed test plan, test instructions, and calculation packages used for the tests documented in this report.

3.2 Stack Tests

The tests described in the following subsections were conducted under scale flow conditions between 50% and 125% of the design flow condition designed for each stack, which were listed in Table 2.2. The test matrix included with the test plan described the minimum number of tests that were planned for each stack. The actual number of tests typically differed from the test plan because tests were added to confirm results that had to be repeated.

Before conducting the tests to determine whether the four qualification criteria described in Section 1.1 were met for each stack, two other measurement sets were made. First, the major features of the stack were measured. The longitudinal distance from the fans to the bends, duct reducers, and ports were determined in addition to the duct diameter at each measurement port. The second set of measurements determined the fan frequency settings needed to achieve the desired flow rates. For these measurements, the location within the duct cross section that had velocity measurements closest to the mean velocity was determined for Port 2. Then, velocity measurements were made at this single measurement point at 5-Hz increments in the fan frequency setting. By developing a frequency vs. velocity relationship for the scale model stack, the frequency setting needed to achieve the flow conditions could be pre-determined.

Measurements were made at specific locations within the duct for each of the four qualification criteria tests described in the following subsections. The number and distance between measurement points was based on the U.S. Environmental Protection Agency (EPA) procedure described in 40 CFR 60, Appendix A, Method 1, for circular stacks. For a 12- to 24-in. duct diameter, eight traverse points are required at the relative positions shown in Figure 3.1. Measurements also were made at the centerpoint. In lieu of making the two measurement points nearest to the walls at 3.2% of the duct diameter from the duct walls, the minimum distance from the wall was set to 0.5 in., as prescribed by EPA Method 1. The measurement point closest to the port was Point 1, while the point farthest from the port was Point 8.

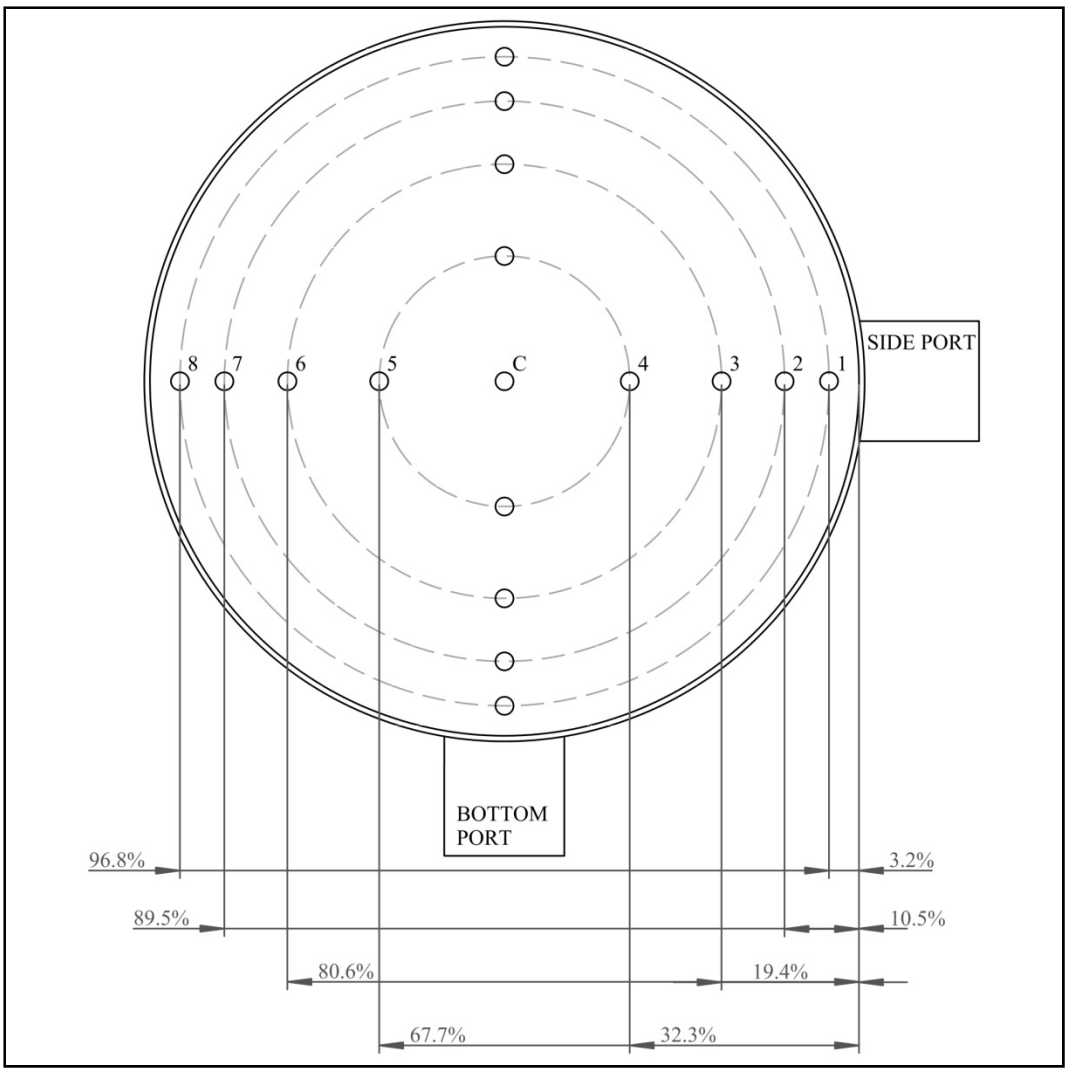

Figure 3.1. Cross Section of the Duct at the Testing Ports with Measurement Points

3.2.1 Velocity Uniformity

The uniformity of air velocity at the stack monitoring location indicates whether the momentum in the stack is well mixed. The method used to conduct the velocity uniformity tests was based on 40 CFR 60, Appendix A, Method 1. The velocity uniformity criterion is that the %COV should be less than 20% in the center two-thirds of the duct (measurement points 2 through 7).

For each run, three air velocity readings were obtained at each of the measurement points across the cross section of the duct. The measured velocity was the average of the three readings. The measured velocity for each point was used to determine the mean and standard deviation of the velocity across the cross-sectional plane. The %COV (a.k.a., the percent relative standard deviation) was calculated as 100 times the standard deviation divided by the mean.

Air velocity measurements were made using a handheld thermal anemometer (TSI, Model 9545, Shoreview, Minnesota). Duct air temperature measurements also were made with the handheld thermal

anemometer. The thermal anemometer reports velocity in standard feet per minute, with standard conditions defined as 1 atm and 70°F. Figure 3.2 shows the thermal anemometer used for this test. The procedure EMS-JAG-04 and test instructions TI-RPP-WTP-676, TI-RPP-WTP-689, and TI-WTPSP-642 were followed to conduct this test for each of the three scale models.

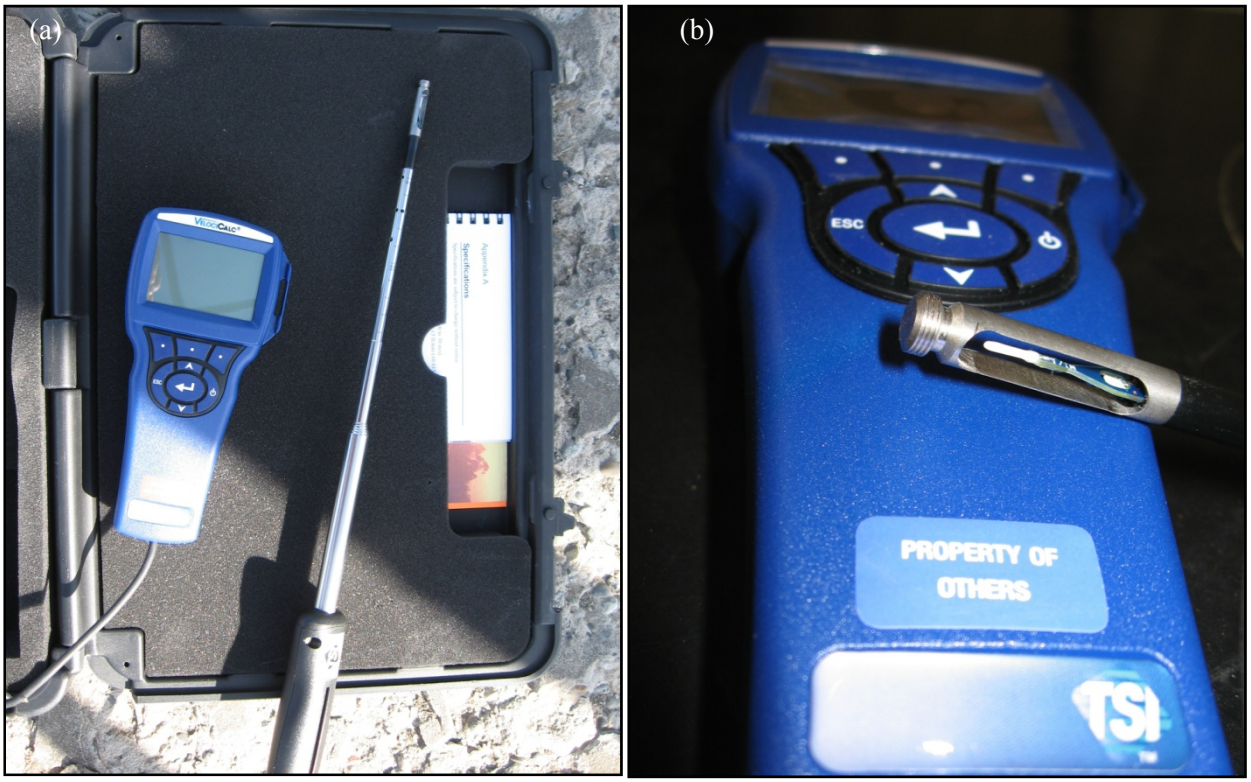

Figure 3.2. Equipment Used for the Velocity Uniformity Test: (a) Thermal Anemometer and (b) Close-Up View of Thermal Anemometer Probe Tip

3.2.2 Flow Angle

The air velocity vector approaching the sample nozzle should be aligned with the axis of the nozzle within an acceptable range so that the sample extraction performance is not degraded. The test method is based on 40 CFR 60, Appendix A, Method 1, Section 11.4, "Verification of the Absence of Cyclonic Flow." The term "flow angle" refers to the angle between the velocity vector of the flow in the duct and the axis of the sampling nozzle. For the stack testing activities, the flow angle was measured at a grid of nine points across two axes in a cross section of the duct (see Figure 3.1). The qualification criterion for the flow angle test is that the average angle should not exceed 20°.

The flow angle measurements were made using an S-type Pitot tube (Dwyer Instruments, 160S-36, Michigan City, Indiana) attached by flexible tubing to a slant-tube manometer (Dwyer Instruments, 400-5, Michigan City, Indiana) and an angle-indicating device attached to the sampling port as shown in Figure 3.3. For this test, the S-type pitot tube was rotated so that the planes of the two open ends of the two tubes are parallel to the long axis of the duct. The pitot tube is then rotated about its long axis until the differential pressure across the open ends of the tubes reads zero on the manometer. The rotation angle is read from the angle indicating device. The measured flow angle for each point is the average of

the three readings. These measured values are used to calculate the mean absolute value of the flow angle across the duct. The procedure EMS-JAG-05 and test instructions TI-RPP-WTP-677, TI-RPP-WTP-689, and TI-WTPSP-018 were used to conduct this test for each of the three scale models.

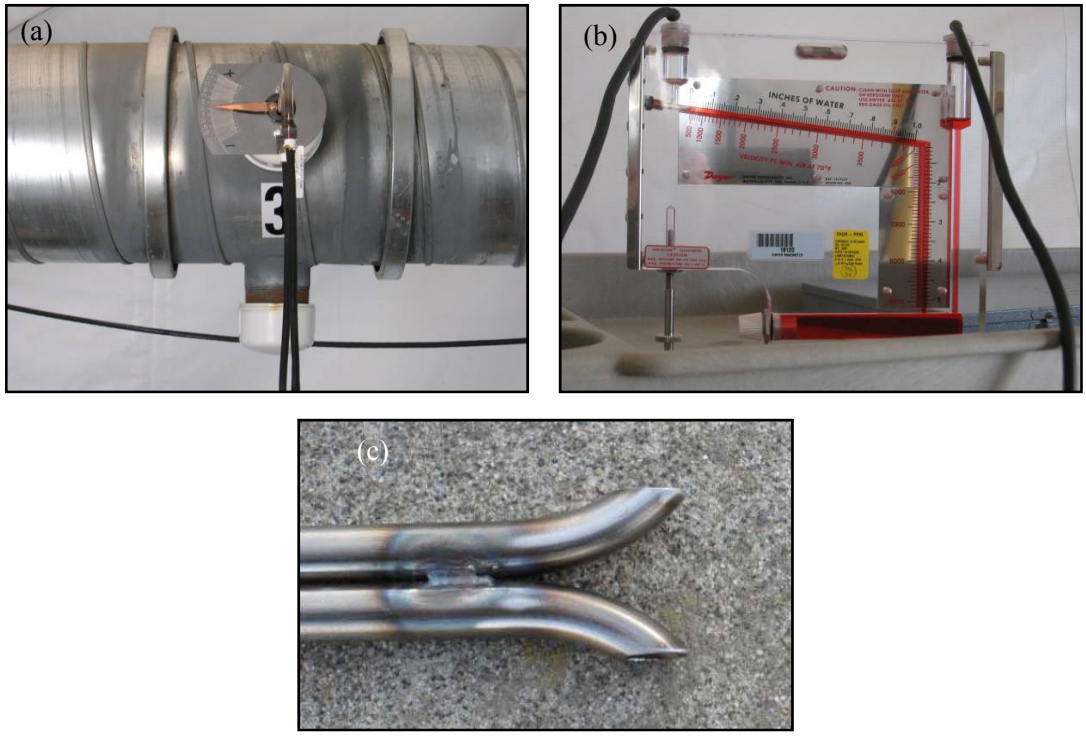

Figure 3.3. Equipment Used for the Flow Angle Test: (a) S-type Pitot Tube Inserted in a Measurement Port with the Protractor Plate, (b) Slant-Tube Manometer, and (c) Openings at Tip of S-Type Pitot Tube

3.2.3 Gaseous Tracer Uniformity

The gaseous contaminant concentration uniformity was demonstrated using the tracer gas sulfur hexafluoride (SF_6). A compressed gas cylinder and a flow controller were used to deliver a constant stream of SF_6 into the duct. The gaseous tracer was typically injected into the duct at a point downstream of the fans. Figure 3.4 shows the injection locations with an injection probe positioned in the port. For separate test runs, the injection probe is positioned at one of five different locations in the duct cross section as illustrated in Figure 3.5. For some tests, just the centerline position is used. The remaining four injection locations are within a specified distance of the duct wall. For a nominally 12-in.-diameter duct, the four "wall" injection locations were located within 2.4 in. of the wall.

For each test run, the tracer concentration was read three times at each of the measurement points across the duct. The measured concentration for each point is the average of the three readings. These measured concentrations are used to calculate the overall mean, standard deviation, and %COV. These calculations also are performed just for the measurement points in the center two-thirds of the duct. The qualification criteria for the gaseous tracer test are that 1) the %COV should be ≤20% within the center two-thirds of the duct and 2) the concentration at any measurement point should not deviate from the overall mean by more than 30%.

Figure 3.4. Equipment Used for the Gaseous Tracer Injection: (a) Injection Probe Installed in the HV-S1 Scale Model and (b) Cylinder of Pure SF_6 with Regulator

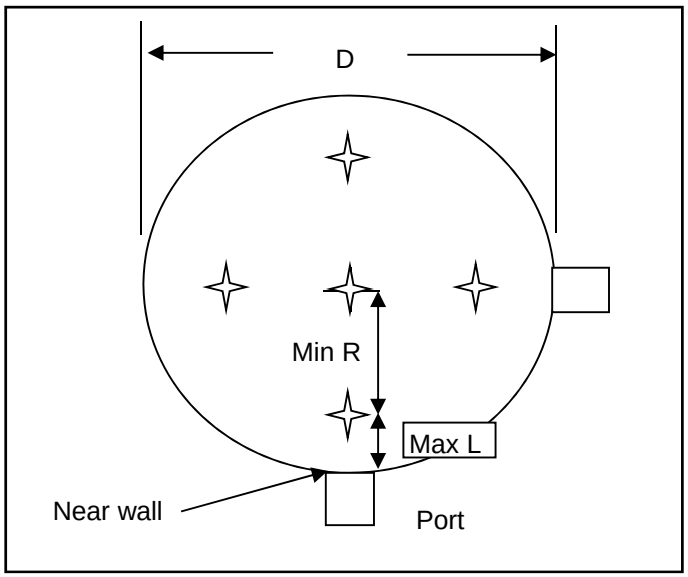

Figure 3.5. Illustration of Five Injection Points in a Circular Duct. Note: Max L is the maximum distance from the wall, which is 20% of the hydraulic diameter. Therefore, Min R, the minimum radius from the duct center, is 80% of the hydraulic diameter. In the case of a round duct, the hydraulic diameter is equal to the physical diameter (D).

A photoacoustic gas analyzer (Brüel & Kjær, Model 1302, Ballerup, Denmark) was used to measure tracer gas concentrations. The concentration variation is the important result for this test, so calibration bias is not important in the test results. However, the analyzer response was checked with calibration standards before and after conducting the test series (as well as weekly during the test series) to verify an adequate instrument response. The response was considered acceptable if the concentration from the instrument was within 10% of the calibration standard.

A simple probe was used to extract the sample and deliver it to the gas analyzer. A small pump drew air from within the stack through the probe. The gas analyzers then sampled the air from the sample line for analysis. Figure 3.6 shows the equipment setup for this test. The procedure EMS-JAG-01 and the test instructions TI-WTPSP-070, TI-WTPSP-078, and TI-WTPSP-084 were used to conduct this test for each of the three scale models.

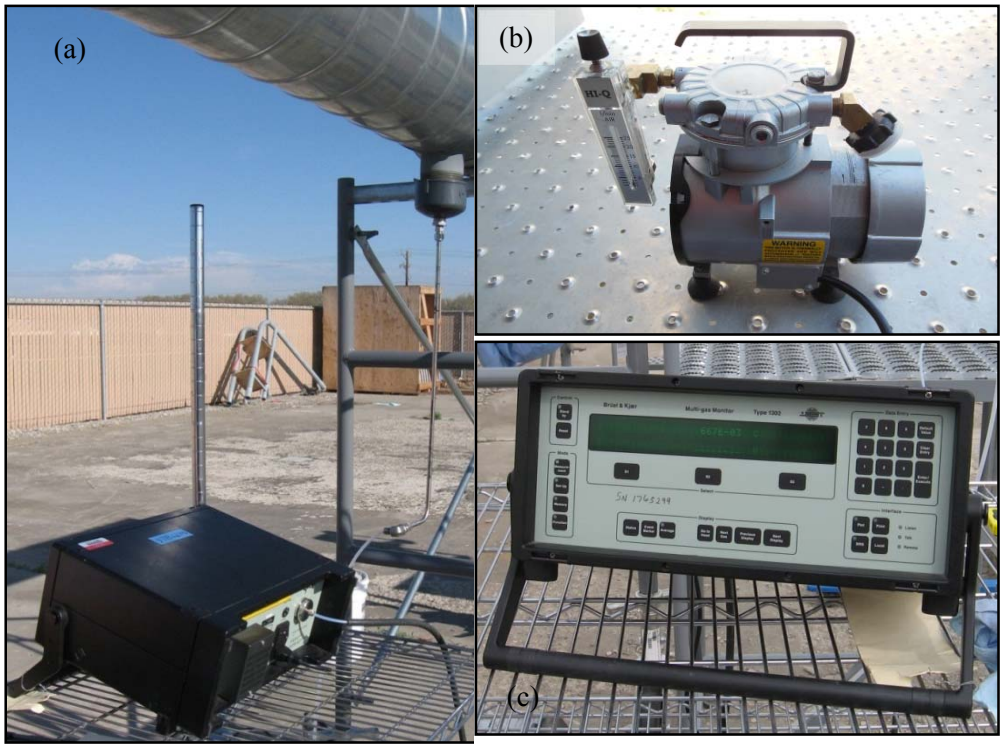

Figure 3.6. Equipment Used for the Gaseous Tracer Sampling: (a) Simple Sampling Probe Installed in a Port, (b) Sampling Pump, and (c) Gas Analyzer

3.2.4 Particle Tracer Uniformity

The uniformity of the particulate contaminant concentration was demonstrated using polydisperse pump oil particles as a particle tracer. Vacuum pump oil was drawn into a spray nozzle (driven by compressed air) housed in a plastic chamber. These aerosol particles were injected into the duct air at an injection point downstream of the fans as shown in Figure 3.7. Figure 3.7 shows the equipment setup for an aerosol injection in the IHLW-S1 scale model stack. The plastic chamber and spray nozzle assembly also is referred to as the aerosol generator. The aerosol was injected at the centerline of the duct, and this test was repeated to gain some sense of the variability of the results.

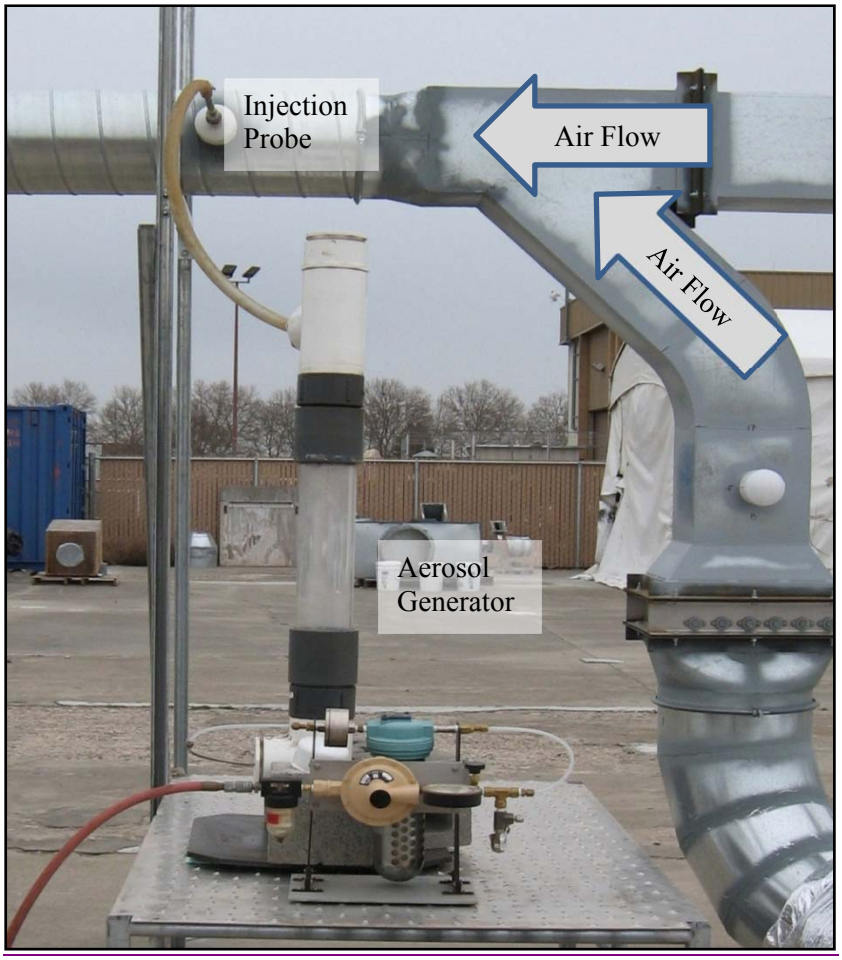

Figure 3.7. Equipment Used for Particle Injection (IHLW-S1)

The concentration of the particles is measured at the sampling grid points with a calibrated optical particle counter (OPC) (Hach, Met-One Model 3415, Loveland, Colorado). A simple probe was used to extract the sample and deliver it to the OPC. Figure 3.8 shows the sampling setup with the simple probe connected to the OPC. To identify potential inconsistencies in the aerosol output, tests were conducted with a reference instrument measuring the particle concentration at the centerpoint at a location downstream of the test port. During the first aerosol tests conducted in this group (PT-1 through PT-7 of IHLW-S1), the reference probe was slightly longer than the measurement probe, as shown in Figure 3.9. For consistency, a probe identical to the measurement probe was fabricated, and the majority of tests were conducted with probes of identical dimension for the measurement and reference locations. Figure 3.9 also shows the reference probe installed on the outlet of the HV-S2 stack, which does not have a port downstream of the measurement port. The OPC sorts the particles into six size channels. As mentioned in Section 1.1, the particles of interest have an AD of 10 μm. Therefore, only data in the 9- to 11-μm channel of the OPC were used.

The particle concentration was read three times at each of the measurement points across the cross section of the duct. The measured concentration for each point is the average of the three readings. From these measurements, the overall mean standard deviation, and %COV were calculated for all of the points

and also just for those within the center two-thirds of the duct. The qualification criterion for the particle tracer test is that the %COV should be less than or equal to 20% within the center two-thirds of the duct. The procedure EMS-JAG-02 and test instructions TI-RPP-WTP-679, TI-RPP-WTP-691, and TI-WTPSP-021 were used to conduct this test for each of the three scale models.

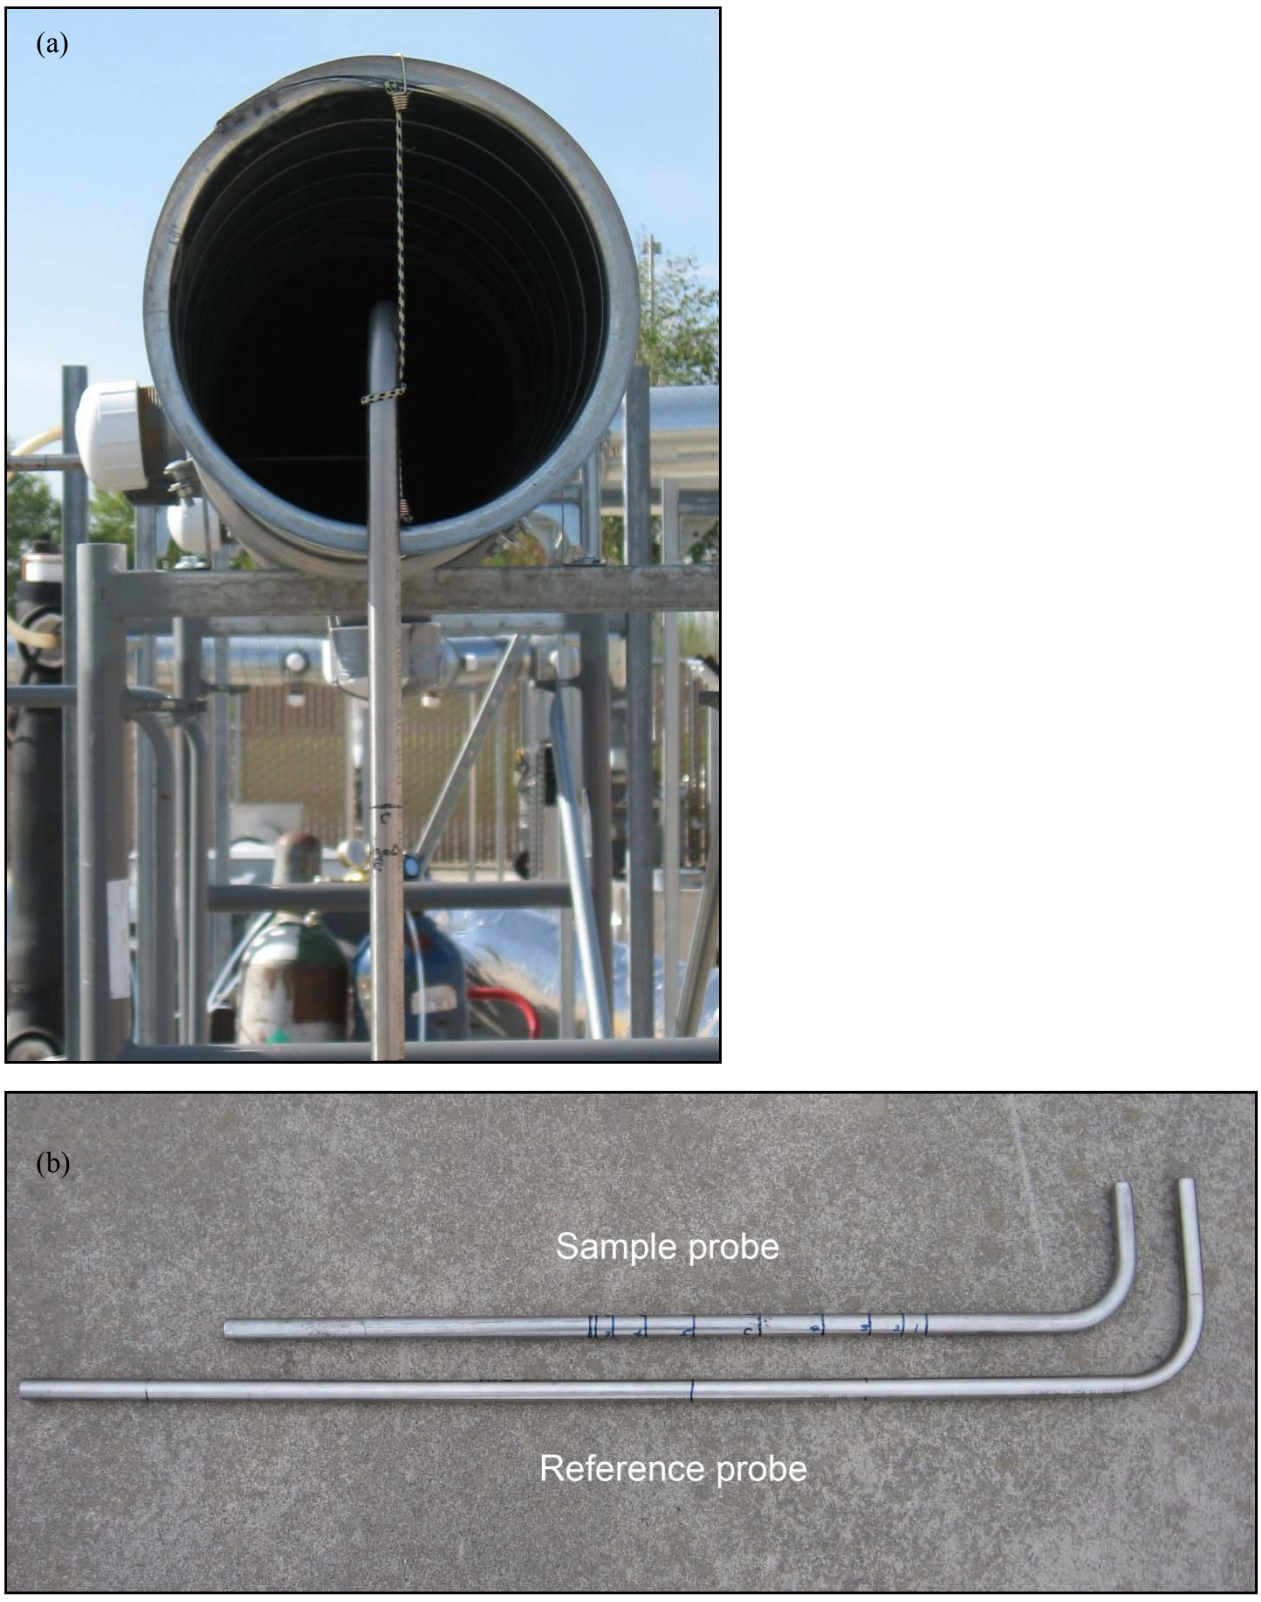

Figure 3.9. Probes Used for the Particle Sampling: (a) Reference Probe Installed in Outlet of HV-S2 Scale Model and (b) Sample and Reference Probe used in Initial Particle Tests. Subsequent tests used two probes identical to the sample probe shown here.

4.0 Stack Testing Results

This section summarizes the results of the stack testing activities for the three scale model stacks in Group 3-4 (HV-S1, HV-S2, and IHLW-S1). The primary, reportable results are the data and data calculations to confirm that the requirements of the ANSI/HPS N13.1-1999 standard have been met. Independent reviews were performed to verify the data transcription and calculations. These calculations were performed using Microsoft Excel (2007, 2010) and documented in computer-assisted calculation packages (CCPs) in accordance with WTPSP procedures. The final data sheets are included in Appendices A through C. Appendix E contains a list of supporting documentation (such as the test plan and test instructions) used with this scale model test group. Each of the Group 3-4 scale model stacks underwent a series of velocity uniformity tests (designated VT), flow angle tests (designated FA), gas tracer tests (designated GT) and particle tracer tests (designated PT). Tables summarizing the results of tests for each scale model are presented in subsections of this chapter. During some tests the, scale model velocity values were higher than the actual stack flow for the conditions the test was meant to represent. This is acceptable because the DV value was still within a factor of six of the stack design values, and the facility flow conditions are estimates and may vary significantly from the design conditions at times for a variety of reasons.

4.1 HV-S1 Stack Results

Data tables, data plots, summary tables of the data for Test Ports 1 and 2 for HV-S1 flow angle, velocity, gas tracer, and particle tracer test results are presented in the following subsections. Some test combinations were repeated (i.e., performed more than once at different times) to quantify the testing and measurement uncertainty.

4.1.1 HV-S1 Velocity Uniformity

The initial test to determine the fan frequency setting for the HV-S1 model is included in Appendix A, Subsection A.1. Table 4.1 lists the results for the velocity uniformity tests performed on the scale model HV-S1 stack. In all cases, the results were well within the criterion of %COV values ≤20%. COV (%COV) values were typically less than 5%, although they ranged from 2.4 to 6.6%. The velocity through the stack ranged from 1136 to 2782 sfpm (883 to 2162 scfm) with one fan operating.

Table 2.2 lists the desired range of minimum scale model flow rates as 1027 to 2361 sfpm (807 to 1854 scfm). The desired testing conditions were between the minimum scale model flow rate and the actual stack velocity. The scale model test conditions meet both the Reynolds number and DV criteria required to represent the actual stack with one operating fan. The completed data sheets from these tests are available in Appendix A.2.

Table 4.1. Summary of HV-S1 Velocity Uniformity Tests

Operating Fan(s)	Test Port	Flow Condition	Run No.	Flow (scfm)	Velocity (sfpm)	%COV
A	2	Max	VT-1	2009	2585	3.6
			VT-13	1939	2494	2.8
			VT-14	1963	2526	3.4
		Norm	VT-15	1787	2299	3.9
			VT-16	1778	2288	3.5
		Min	VT-2	883	1136	4.0
B	1	Min	VT-12	911	1172	5.4
	2	Max	VT-3	2105	2708	6.1
			VT-4	2128	2738	4.8
			VT-5	2162	2782	6.6
		Norm	VT-9	1900	2444	4.4
			VT-10	1952	2512	6.4
			VT-11	1881	2420	4.3
			VT-13	1939	2494	2.8
		Min	VT-6	894	1150	5.3
			VT-7	921	1184	5.1
			VT-8	940	1210	6.2

Note: Individual or replicate sets of tests are alternately shaded and unshaded.

4.1.2 HV-S1 Flow Angle

Table 4.2 lists the results for the flow angle tests performed on the scale model HV-S1 stack. The results for all tests were well within the criterion of flow angle values ≤20°. Typical results were between 3° and 5°. The completed data sheets from these two tests are available in Appendix A, Subsection A.3.

Table 4.2. Summary of HV-S1 Flow Angle Tests

Operating Fan(s)	Test Port	Flow Condition	Run No.	Approximate Air Velocity (sfpm)	Mean Absolute Flow Angle (°)
A	2	Max	FA-1	2698	3.4
		Min	FA-2	1141	3.1
B	2	Max	FA-3	2824	4.2
			FA-4	2881	3.4
		Norm	FA-5	2427	4.7
		Min	FA-6	1170	3.4
	1	Max	FA-7	2669	4.2

Note: Individual or replicate sets of tests are alternately shaded and unshaded.

4.1.3 HV-S1 Gaseous Tracer Uniformity

During the gas tracer testing, the response of the gas analyzer was checked against calibration standards of appropriate concentrations, and the results met the requirements of the procedure. Table 4.3 lists the results for the gaseous tracer uniformity tests performed on the scale model HV-S1 stack for test Ports 1 and 2 and the tracer injection at Port C. In all cases, the tracer was well mixed, with results well

within the criteria of %COV values ≤20% and absolute values of maximum deviation ≤30%. COV values were typically around 2%, with maximum deviation values typically around 4%. The "worst" mixing was observed for one of the bottom injection positions with the maximum velocity condition (GT-8). This test had nearly 5% COV and 8% maximum deviation from the mean concentration, which is still well within the bounds of the criteria. However, tests repeated at these conditions were nearly half of the GT-8 result, implying that GT-8 results may simply reveal the variability of the testing itself. Test results for GT-9 and GT-17 are not shown in Table 4.3 because the average velocity was well outside of the maximum flow conditions for the actual stack. The completed data sheets from these tests are available in Appendix A, Subsection A.4.

Table 4.3. Summary of HV-S1 Gas Tracer Uniformity Tests at Test Ports 1 and 2

Operating Fan(s)	Test Port	Flow Condition	Injection Port & Location	Run No.	Avg Velocity (sfpm)	%COV	Abs % Max Dev. from Mean
A	2	Max	C Center	GT-14	2543	1.3	3.4

	2	Min	C Center	GT-3	1101	1.8	4.1

Note: Individual or replicate sets of tests are alternately shaded and unshaded.

4.1.4 HV-S1 Particle Tracer Uniformity

Table 4.4 lists the results for the particle tracer uniformity tests performed on the scale model HV-S1 stack. Tests were conducted with the two fans running separately. The completed data sheets from these tests are available in Appendix A, Subsection A.5.

During some runs, the output of the aerosol generator varied with time. To observe the particle generator performance during a test run, a second OPC was set up to sample from the stack centerline, at an unused test port. Figure 4.1 shows the measurement data superimposed on the reference OPC data from run PT-3. In this case, the reference OPC shows a periodic variability in the aerosol generator output. Consequently, PT-3 results are not listed in Table 4.4. PT-3 was repeated as PT-5, and the normalized %COV result for PT-5 was well within 20%.

Previous testing has shown that the measured particle concentration was usually higher through the bottom port. A series of troubleshooting tests was unsuccessful in determining a consistent cause of this behavior. However, to mitigate errors, the concentration bias encountered between the two traverse

directions at the measurement ports was removed by adjusting the data from the traverse with the lower concentration upward by a factor to match the concentrations at the center of the duct (the common point between the two traverses). These results were then termed "normalized."

The result of normalization is illustrated in Figure 4.2 for PT-6, the side traverse data were adjusted up by a factor of 1.28. For tests where there was a large discrepancy between the concentrations measured by the two traverses, the %COV without normalization applied may exceed the qualification criterion. However, normalizing the data, helps meet the particle-tracer uniformity criterion of %COV ≤20%. Table 4.4 shows the %COV values both with and without normalization applied.

Table 4.4. Summary of HV-S1 Particle Tracer Uniformity Tests

Operating Fan	Injection Port & Location	Test Port	Flow Condition	Run No.	Avg Velocity (sfpm)	Non-Normalized %COV	Normalized %COV
A	C Center	2	Max	PT-5	2546	23.3	8.4
			Min	PT-4	1066	20.6	11.7
B	C Center	1	Max	PT-8	2933	25.1	14.8
		2	Max	PT-1	2613	16.5	11.1
			Norm	PT-7	2396	17.0	9.5
			Min	PT-2	931	12.7	4.4
				PT-6	1298	13.5	4.6

Note: Individual and replicate sets of tests are alternately shaded and unshaded.

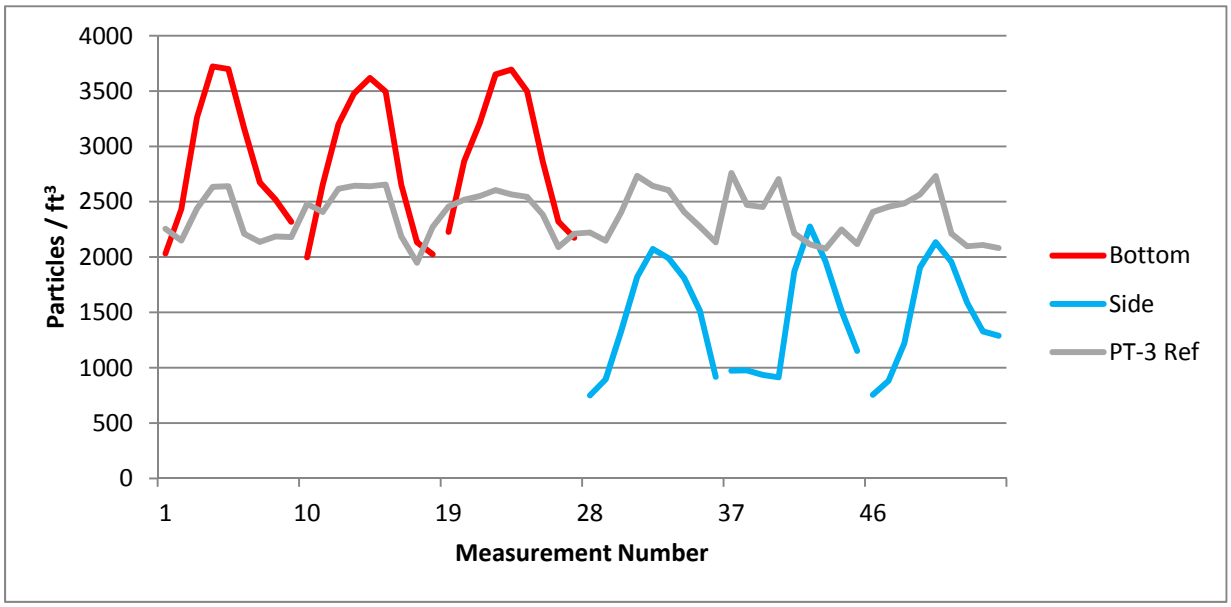

Figure 4.1. Measurement and Reference Particle Test Data from PT-3 on the HV-S1 Stack. Colored lines represent measurement traverses from the side and bottom ports, while the grey line represents the reference concentration at the centerpoint at a downstream location. This plot is an example of variability in the aerosol production and a systematic bias between the bottom and side port measurements.

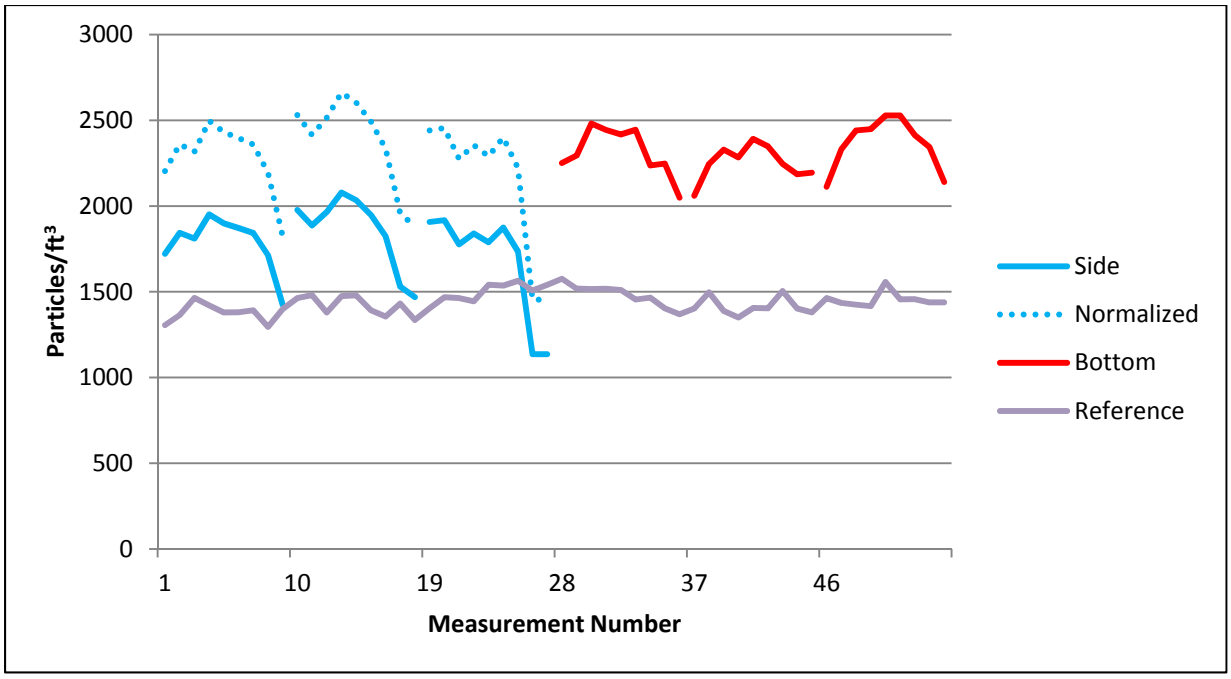

Figure 4.2. Measurement and Reference Particle Test Data from PT-6 on the HV-S1 Stack. Non-normalized data are shown with solid lines while normalized data are shown with dotted lines. Data collected from the side port have been adjusted up by a factor of 1.28.

4.2 HV-S2 Stack Results

Data tables, data plots, and summary tables of the data for Test Ports 1 and 2 for HV-S2 flow angle, velocity, gas tracer, and particle tracer test results are presented in the following subsections. Some test combinations were repeated (i.e., performed more than once at different times) to provide for quantifying the testing and response measurement uncertainty.

4.2.1 HV-S2 Velocity Uniformity

Table 4.5 lists the results for the velocity uniformity tests performed on the scale model HV-S2 stack. In all cases, the results were well within the criterion of %COV values >20%. The velocity in the stack ranged from 1077 to 2877 sfpm (837 to 2236 scfm). Table 2.2 lists the desired range of minimum scale model flow rates as 1047 to 2203 sfpm (840 to 1730 scfm). The desired testing conditions were between the minimum scale model flow rate and the actual stack velocity. With these flow conditions, the scale model meets both the Reynolds number and DV criteria required to represent the actual stack. The completed data sheets from these tests are available in Appendix B, Subsection B.2.

Table 4.5. Summary of HV-S2 Velocity Uniformity Tests

Operating Fan(s)	Test Port	Flow Condition	Run No.	Flow (scfm)	Velocity (sfpm)	%COV
A	2	Max	VT-10	2236	2877	2.5
		Normal	VT-1	1810	2329	2.7
		Min	VT-3	838	1078	3.5
			VT-4	940	1210	3.5
B	2	Max	VT-2	2028	2609	4.7
			VT-9	2174	2796	4.5
		Normal	VT-6	1909	2456	7.8
			VT-7	1895	2437	6.2
			VT-8	1873	2409	4.7
		Min	VT-5	837	1077	5.1

Note: Individual and replicate sets of tests are alternately shaded and unshaded.

4.2.2 HV-S2 Flow Angle

Table 4.6 lists the results for the flow angle tests performed on the scale model HV-S2 stack. The results for all tests were well within the criterion of flow angle values ≤20°. Flow angles when Fan A was operating were markedly smaller than when Fan B was operating. Fan A flow angles ranged from 3.9° to 7.1°, while Fan B flow angles range from 10.3° to 12.5°. The geometry of the stack, in which the Fan B duct intersects the main stack ducting at a horizontal angle, followed immediately by a jog in the stack, is likely the source of the higher flow angles. The completed data sheets from these tests are available in Appendix B, Subsection B.3.

Table 4.6. Summary of HV-S2 Flow Angle Tests

Test Port	Operating Fan	Flow Condition	Run	Approx. Air Velocity (sfpm)	Flow Angle (Degrees)
		Max	FA-5	3065	7.1
		Norm	FA-2	2443	3.9
		Min	FA-1	1063	6.1
	B	Max	FA-4	2627	11.0
			FA-8	3008	12.5
		Norm	FA-3	2471	10.3
		Min	FA-6	1084	11.5
			FA-7	1195	11.1

Note: Individual or replicate sets of tests are alternately shaded and unshaded.

4.2.3 HV-S2 Gaseous Tracer Uniformity

During the gas tracer testing, the response of the gas analyzers was checked against calibration standards of appropriate concentrations, and the results met the requirements of the procedure.

Table 4.7 lists the results for all of the gaseous tracer uniformity tests performed on the scale model HV-S2 stack. No contingency port was tested for this scale model; all tests were performed at Test Port 2.

In all cases, the tracer was well mixed, with results well within the qualification criteria of %COV values less than 20% and absolute value of maximum deviation less than 30%. COV values were typically less than 4%, with maximum deviation values typically less than 10%. The least amount of mixing was observed for the Fan A maximum flow conditions. For this condition, the COV ranged from 4.0% to 7.2%, while the deviation from the mean ranged from 8.5% to 14.2%. It is likely that Fan B conditions had increased mixing compared with similar Fan A conditions because of the geometry of the stack; the flow from Fan B enters the main stack from an angle, thus increasing the turbulence and mixing of the tracer near the injection point. The completed data sheets are available in Appendix B, Subsection B.4.

Table 4.7. Summary of HV-S2 Gas Tracer Uniformity Tests at Test Port 2

Test Port	Operating Fan	Flow Condition (%)	Injection Port & Location	Run No.	Avg Velocity (sfpm)	%COV	Absolute % Max. Dev. from Mean
2	A	Max	E Center	GT-9	3103	7.2	14.2
				GT-10	3052	5.0	11.9
				GT-11	3060	4.2	10.5
				GT-12	3094	4.0	8.5
	A	Min	E Center	GT-1	1084	4.0	12.5
	B	Max	E Center	GT-3	2651	2.2	4.6

	B	Min	E Center	GT-2	1065	1.8	4.3

Note: Individual or replicate sets of tests are alternately shaded and unshaded.

4.2.4 HV-S2 Particle Tracer Uniformity

Table 4.8 lists the normalized and non-normalized %COV for each run at Test Port 2. In all cases, the uniformity criterion was met. As was the case for the gaseous tracer uniformity, the poorest mixing was observed under the Fan A Max condition. The %COVs for this condition were 12.1% and 13.0%. Other test conditions had COV values between 5.3 and 10.7%. The completed data sheets from these tests are available in Appendix B, Subsection B.5.

Table 4.8. Summary of HV-S2 Particle Tracer Uniformity Tests

Operating Fan	Injection Port & Location	Test Port	Flow Condition	Run No.	Avg Velocity (sfpm)	Non-Normalized %COV	Normalized %COV
A	E Center	2	Max	PT-1	3069	15.5	13.0
			Norm	PT-8	2434	18.6	10.7
			Min	PT-4	1151	9.8	9.3
B	E Center	2	Max	PT-2	3073	18.0	8.7
			Norm	PT-5	2413	25.3	10.0
				PT-6	2403	34.9	6.1
			Min	PT-3	1034	18.4	5.3

Note: Individual or replicate sets of tests are alternately shaded and unshaded

As was discussed for the HV-S1 scale model tests, the instrument response would change as it was moved between the bottom and side ports. Figure 4.3 shows the concentration profiles for the six traverses (trials) for PT-1. The concentration profile was clearly much lower for the side port as compared to the bottom port. The data were normalized as described in Section 4.1.4.

Although the aerosol generator was operated for 30 to 60 min prior to collecting measurements to allow aerosol output to stabilize, there were instances where the aerosol generator output changed during a run. For example, Figure 4.4 shows that the concentration declined by 50% during Run PT-7. The decline occurred during the side port measurements and then remained fairly constant for the bottom traverse. The PT-7 results have been omitted from Table 4.8 because of the decreasing aerosol output during the side traverses.

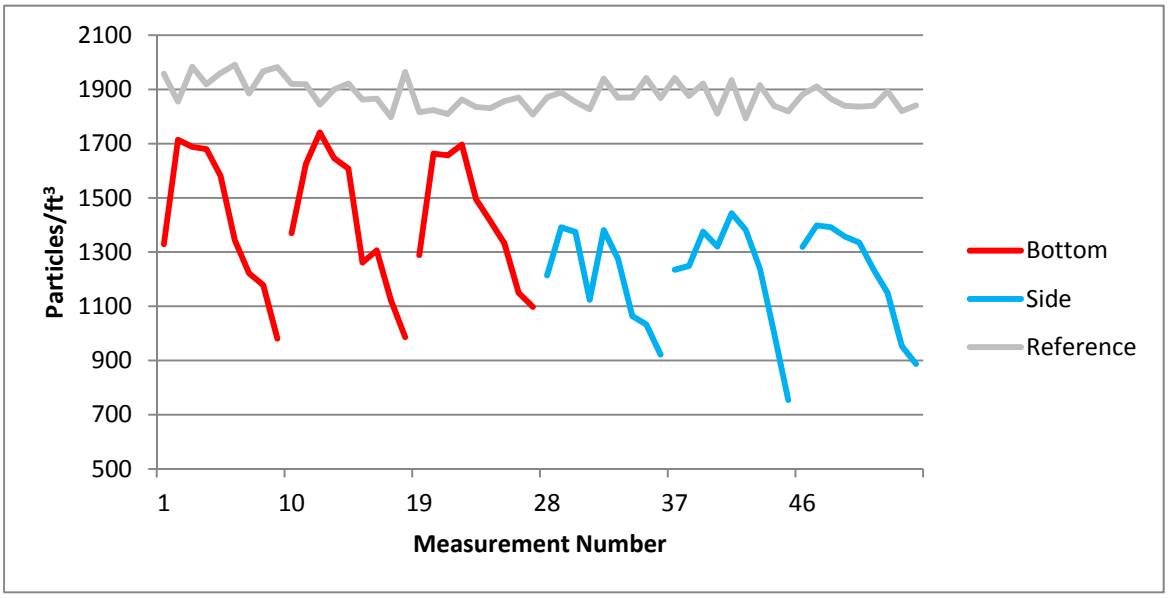

Figure 4.3. Measurement and Reference Particle Tracer Test Data from PT-1 of HV-S2. Colored lines represent measurement traverses from the side and bottom ports, while the grey line represents the reference concentration at the centerpoint at a downstream location. This plot is an example of very stable aerosol production and a small systematic bias between bottom and side port measurements.

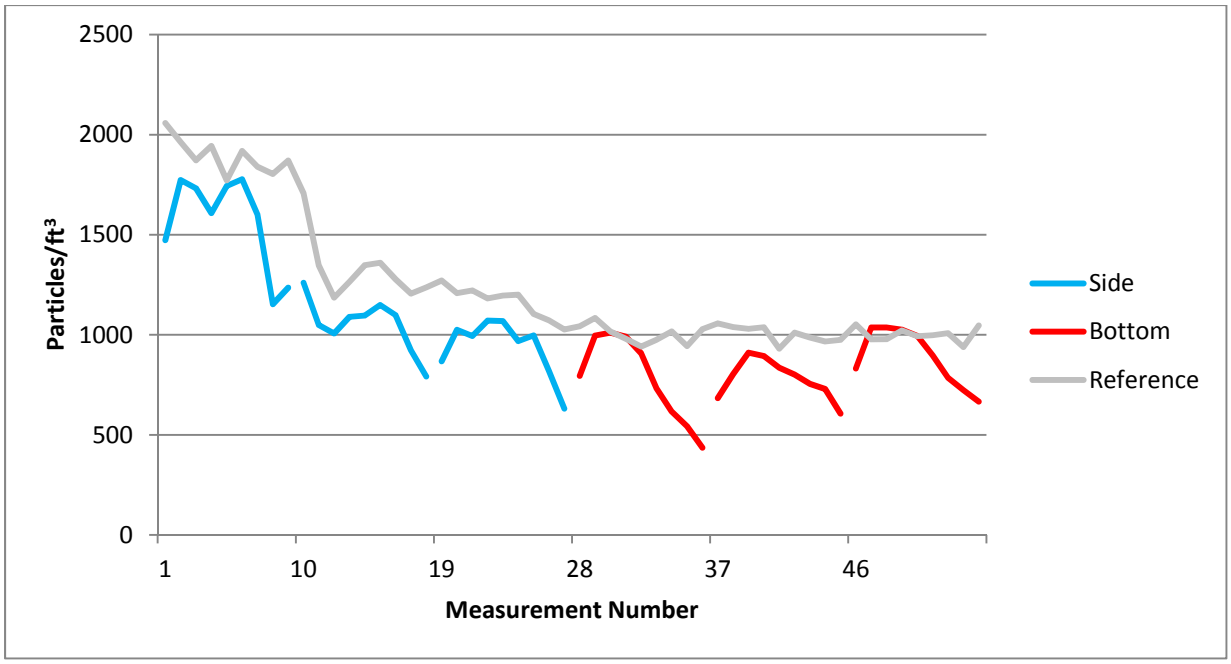

Figure 4.4. Measurement and Reference Particle Tracer Test Data from PT-7 of HV-S2. Colored lines represent measurement traverses from the side and bottom ports, while the grey line represents the reference concentration at the centerpoint at a downstream location. This plot is an example of a typical decline in aerosol production.

4.3 IHLW-S1 Stack Results

Data listings, data plots, and summary tables for IHLW-S1 flow angle, velocity, gas tracer, and particle tracer test results are presented in the following subsections. Some test combinations were repeated (performed more than once at different times) to provide for quantifying the testing and response measurement uncertainty.

4.3.1 Velocity Uniformity

The initial test to determine the fan frequency setting for the IHLW-S1 model to achieve the desired flow conditions is included in Appendix C, Subsection C.1. Fifteen velocity uniformity runs were performed for the IHLW-S1 model. Table 4.9 lists the results for all of the runs. Table 2.2 lists the range of minimum scale model flow rates as 401 to 839 sfpm (315 to 659 scfm). The desired testing conditions were between the minimum scale model flow rate and the actual stack velocity. With these flow conditions, the scale model meets both the Reynolds number and DV criteria required to represent the actual stack with one operating fan.

All results were within the qualification criterion of %COV values ≤20%. COV values were typically less than 8%, with values ranging from 4.2 to 10.0%COV. The largest COV value occurred for a minimum flow condition. The completed data sheets from these tests are available in Appendix C, Subsection C.2.

Table 4.9. Summary of IHLW-S1 Velocity Uniformity Tests

Operating Fan(s)	Test Port	Flow Condition	Run No.	Flow (scfm)	Velocity (sfpm)	%COV
A	2	Max	VT-1	1725	2219	4.6
			VT-11	1321	1700	4.7
			VT-12	1541	1983	4.2
		Norm	VT-2	724	931	6.1

			VT-13	1390	1788	5.3
			VT-14	1410	1814	5.0
		Norm	VT-5	750	965	8.2
			VT-10	1294	1664	5.9
		Min	VT-6	341	439	10.0
	1	Max	VT-3	1881	2420	4.6
			VT-15	1557	2004	5.2

Note: Individual and replicate sets of tests are alternately shaded and unshaded.

4.3.2 IHLW-S1 Flow Angle

Table 4.10 lists the results of the flow angle tests for the IHLW-S1 scale model. The qualification criterion of ≤20° was met in all cases. The largest results of 9.3° and 7.3° occurred during tests of moderate flow rates representing maximum flow conditions for both Fan A and Fan B. The completed data sheets from these tests are available in Appendix C, Subsection C.3.

Table 4.10. Summary of IHLW-S1 Flow Angle Tests

Operating Fan	Test Port	Flow Condition	Run No.	Approx. Air Velocity (sfpm)	Mean Absolute Flow Angle (°)
A	2	Max	FA-1	2500	4.0
			FA-8	1797	9.3
		Min	FA-2	500	4.4
B	2	Max	FA-3	2570	3.3
			FA-6	1800	1.9
			FA-7	1775	7.3
		Min	FA-5	500	1.3
	1	Max	FA-4	2590	1.9

Note: Individual and replicate sets of tests are alternately shaded and unshaded.

4.3.3 IHLW-S1 Gaseous Tracer Uniformity

Twenty-seven gaseous tracer tests were conducted on the IHLW-S1 scale model. Table 4.11 lists the test results for the tests that are considered to have valid results. Test run results GT-2 through GT-8 were excluded from the table because the injection probe possibly was possibly positioned improperly. Many of the test results have very low %COV values, which indicates a high level of tracer mixing at

Test Port 2. This result was expected, given the number of bends and duct runs between the injection and sampling points. The completed data sheets from the IHLW-S1 gas tracer tests are available in Appendix C, Subsection C.4.

Table 4.11. Summary of IHLW-S1 Gas Tracer Uniformity at Test Ports 1 and 2

Operating Fan	Test Port	Flow Condition	Injection Point	Run No.	Avg Velocity (sfpm)	%COV	Abs. % Max. Dev. from Mean

			C Center	GT-26	411	1.8	3.5
			C Center	GT-27	832	1.5	3.5

Note: Individual or replicate sets of tests are alternately shaded and unshaded.

4.3.4 IHLW-S1 Particle Tracer Uniformity

Table 4.11 shows the particle tracer uniformity test results without and with normalization applied for the IHLW-S1 scale model. The normalized data show that the qualification criterion (≤20%COV) is met for all of the runs. The completed data sheets from these tests are available in Appendix C, Subsection C.5.

As was observed in most particle tracer tests, the tracer aerosol output can vary with time during the run, and the OPC response can change when the instrument is reoriented. To track the output of the aerosol generator, a second OPC was used as the reference instrument sampling from the stack centerline at another test port throughout the run. PT-3 results were omitted from the table because of highly inconsistent aerosol production. Figure 4.5 shows the data collected from the measurement port during PT-3 along with the concurrent measurement at the center point at Port 1, downstream of the measurement port as a reference. The aerosol production was highly erratic, and the measurement data across the traverses track with the reference data, and does not provide useful information about the stack cross-sectional mixing of particulate tracer. PT-8 has also been omitted from the summary of results

tabulated in Table 4.12 because of a consistent decline in aerosol production throughout the test. PT-8 results are driven primarily by the aerosol production rate, and is not a reliable measure of the stack mixing.

Table 4.12. Summary of IHLW-S1 Particle Tracer Uniformity Tests

Test Port	Operating Fan	Injection Port & Location	Flow Condition (%)	Run No.	Avg Velocity (sfpm)	Non-normalized %COV	Normalized %COV
2	A	C Center	Max	PT-1	2033	15.1	15.2
			Min	PT-7	398	16.7	5.3
	B	C Center	Max	PT-2	2085	8.3	8.5
			Norm	PT-9	849	5.5	3.3
			Min	PT-4	378	9.0	7.9
				PT-6	324	7.7	6.0
1	B	C Center	Max	PT-5	2104	16.6	9.2

Note: Individual or replicate sets of tests are alternately shaded and unshaded.

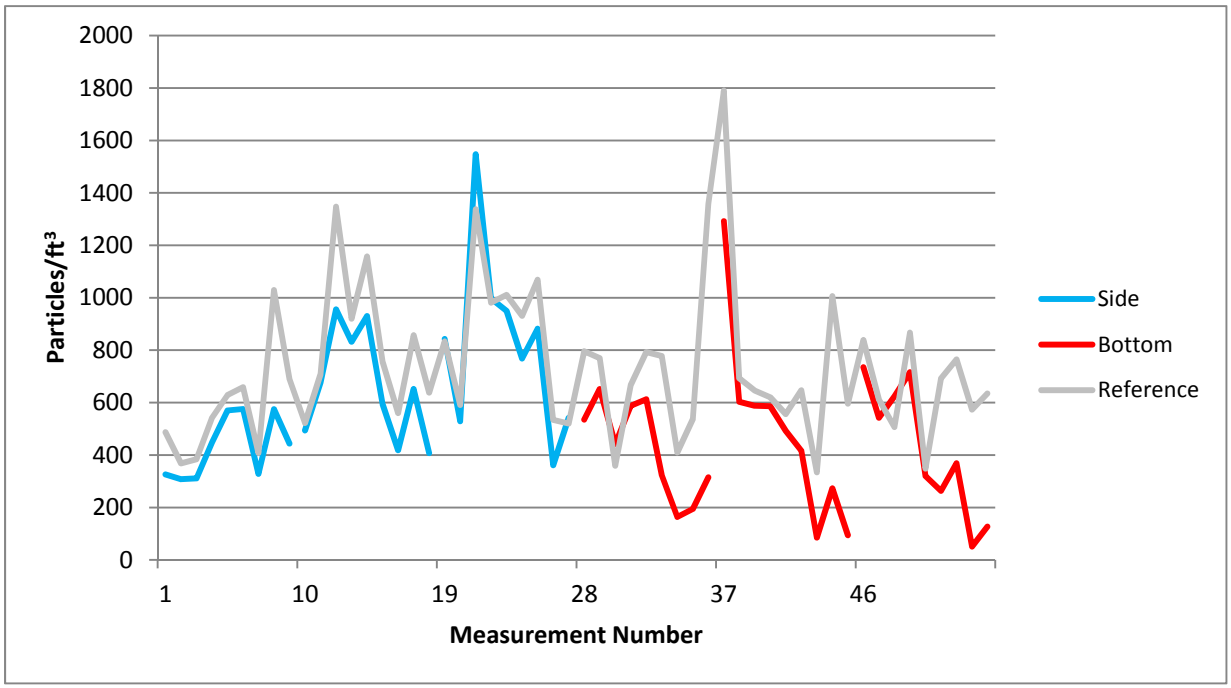

Figure 4.5. Measurement and Reference Particle Tracer Test Data from PT-3 of IHLW-S1. Colored lines represent measurement traverses from the side and bottom ports, while the grey line represents the reference concentration at the center point at a downstream location. This plot is an example of highly erratic aerosol production.

5.0 Conclusions

The results of the tests for each scale model stack in Group 3-4 are summarized in Table 5.1 and Table 5.2. The criteria for sampling probe locations given in ANSI/HPS N13.1-1999, *Sampling and Monitoring Releases of Airborne Radioactive Substances from the Stack and Ducts of Nuclear Facilities,* were met in all cases. These criteria address the capability of the sampling probe to extract a sample that represents the effluent stream. The range of results presented in Table 5.1 for the Group 3-4 stacks covers the designed location for the air sampling probe, Test Port 2.

For the HV-S1 and IHLW-S1 stacks, a limited number of tests were also conducted at a location five duct diameters downstream of the primary location, Test Port 1. This allows for some variability that may occur because of design or construction changes. HV-S2 tests were conducted only at Test Port 2 because of client input that stated that no contingency ports are available for this stack. The results for Test Port 1 are included in Table 5.2. With the exception of the HV-S1 velocity uniformity test, the Test Port 1 conditions represent maximum stack flow conditions. The HV-S1 velocity uniformity test at Test Port 1 was conducted as a minimum flow case.

Table 5.1. Summary of Test Port 2 Results for the Group 3-4 Scale Model Stacks

	Acceptance Criteria	Units	HV-S1	HV-S2	IHLW-S1
Velocity Uniformity	≤20	%COV	2.8 – 6.6	2.5 – 7.8	4.2 – 10
Flow Angle	≤20	Degrees	3.1 – 4.7	3.9 – 12.5	1.3 – 9.3
Gas Tracer Uniformity	≤20	%COV	1.1 – 4.7	1.8 – 7.2	0.9 – 5.8
	≤30	Maximum % Deviation from Mean	2.6 – 7.9	4.3 – 14.2	1.8 – 11.2
Particle Tracer Uniformity	≤20	Normalized %COV	4.4 – 11.7	5.3 – 13	3.3 – 15.2

Table 5.2. Summary of Test Port 1 Results for the Group 3-4 Scale Model Stacks

	Acceptance Criteria	Units	HV-S1	IHLW-S1
Velocity Uniformity	≤20	%COV	5.4[a]	4.6 – 5.2
Flow Angle	≤20	Degrees	4.2	1.9
Gas Tracer Uniformity	≤20	%COV	1.3 – 3.2	0.6 – 3.3
	≤30	Maximum % Deviation from Mean	3.8 – 5.7	1.2 – 6.1
Particle Tracer Uniformity	≤20	Normalized %COV	14.8	9.2

[a] HV-S1 Velocity Uniformity conducted at minimum flow condition. All other tests conducted at maximum flow conditions.

The results at Test Port 1, which is 5 duct diameters downstream of the anticipated sampling location at Test Port 2 tend to be fairly similar to the Test Port 2 results. Without more extensive testing and statistical analysis to determine the effect of distance on the ANSI/HPS N13.1-1999 testing results, quantitative commentary cannot be made. However, qualitatively, the results indicate that there is minor difference between the two locations, and that either location (as well as locations in between) should be sufficient as a qualified sampling location.

Based on these scale model tests, the locations proposed for the air sampling probes in each of the three Group 3-4 stacks meet the requirements of the ANSI/HPS N13.1-1999 standard. Additional velocity uniformity and flow angle tests on the actual stacks will be necessary during cold startup to confirm the validity of the scale model results in representing the actual stacks. In particular, the velocity uniformity test results for the actual stacks must be within 5%COV of the range of results listed above for the scale model so that scale model results can be said to be representative of the stack. For example, if the actual IHLW-S1 stack sampling probe is located in a position corresponding to Test Port 2, the measured velocity uniformity %COV should be between 0.0 and 15%COV (non-negative value for 4.3 - 5 = 0.0, and 10 + 5 = 15). The velocity uniformity test results summarized in Table 5.1 cover a range of flow conditions that are expected to bracket the conditions of the actual stack. For cold startup tests, the DV value and Reynolds number should meet the criteria listed in Section 1 (i.e., DV within a factor of six and Reynolds number >10,000). The velocity uniformity acceptance range would be constructed using the scale model results that correspond to the probe location and fan operating conditions present during the test on the actual stack.

Gas analyzer checked: 4/9/2012 CA 4/11/12

Notes: The B&K analizer may periodicaly show an error message. We push the measurement buttom to get rid of the message and resume measurement. We need to note that thi result in loss of the last data point before the error message occurs. One can redo that point and continue with testing.

JEF 4/12/12

Notes: Wind getting pretty gusty during second traverse. Side, Trial 3, Point 4 discovered the SF6 cylinder was closed. Had been running on back pressure. Appears that delivery of SF6 dropped in one sample cycle. Run trial 4 just in case.

Notes: Compressor pressure 150 psi

The particle generator seems to be very sensitive to ambient temperaturechange. For example, outdoor temperature changes from 56 F to 72 F, the particle number concentration at center raised from ~ 2700 to 3700. Thus, we redid traverse 1st and 2nd for bottom.

SULFUR HEXAFLUORIDE GAS INSTRUMENT CALIBRATION

Site	HV-S2 Model	Instrument	B&K Model 1302
Date/Time	6/19/12 1025	Serial No.	1765299
Testers	CA,JEF	Property No.	WD17210

Setup:
- 7.7 ft B&K sample inlet tube length
- 996 mbar station pressure
- 65 deg F ambient temp analyzer corrects to 20 deg C
- 28 percent RH ambient humidity

Pre-Test background, ppb

Not compensating for water vapor, monitoring task 2

30, 27, 28, 29, 29

Compensating for water vapor, monitoring task 1

8.3, 6.6, 4.3, 5.3, 6.1

SULFUR HEXAFLUORIDE GAS INSTRUMENT CALIBRATION

Site	IHLW-S1 Model	Instrument	B&K Model 1302
Date/Time	4/23/12 7:55AM	Serial No.	1765299
Testers	JEF, CA	Property No.	WD17210

Setup:
- 7.7 ft B&K sample inlet tube length
- 999 mbar station pressure
- 70.7 deg F ambient temp analyzer corrects to 20 deg C
- 34% percent RH ambient humidity

Pre-Test background, ppb

Not compensating for water vapor, monitoring task 2

40.5, 41.2, 43.9, 42.0, 38.1

Compensating for water vapor, monitoring task 1

Appendix D

Flow Unit Conversions

Appendix D

Flow Unit Conversions

Flow units provided by BNI were in actual flow units. For consistency with the measurement equipment used for velocity and flow rate measurements, these were converted to standard flow units. Converting from acfm to scfm was done by simple ratio of the standard temperature (in absolute units, Rankine) to the actual temperature of the stack provided by BNI, as follows:

$$Q_{scfm} = Q_{acfm}\left(\frac{T_{std}}{T_{act}}\right)$$

The table below lists the flow and velocity values provided by BNI as well as the calculated values in standard units.

	Temperature (F)	Air Flow (acfm)	Air Flow (scfm)	Air Velocity (afpm)	Air Velocity (sfpm)
HV-S1					
Single fan—max flow	105	59,300	55,627	3,030	2,833
Single fan –norm flow	93	47,500	45,524	2,419	2,319
Single fan—min flow	59	23,700	24,202	1,207	1,233
HV-S2					
Single fan—max flow	170	63,750	53,631	3,041	2,558
Single fan –norm flow	102	51,000	48,096	2,433	2,294
Single fan—min flow	59	25,500	26,040	1,216	1,242
IHLW-S1					
Single fan—max flow	160	13,100	11,198	2,078	1,776
Single fan –norm flow	102	10,480	9,883	1,662	1,567
Single fan—min flow	59	5,240	5,351	831	849
