Pacific Northwest National Laboratory Richland, Washington 99354

Project Description

Develop novel disease prediction models using deep learning techniques on Electronic Health records (EHR) data, potentially enabling personalized, precision medicine for patient populations.

Abstract

Coordinating patient care using electronic health records (EHR) data presents an exciting but formidable opportunity in data extraction, analysis and modeling. Traditional methods use a manual feature driven approach to model patients with age, family history and symptoms to predict disease outcomes. We propose a novel approach to model patients based on their streaming electronic health records data combined with information from medical knowledge bases, which has been gained over years of medical research. Using a combination of representation learning and long short-term memory (LSTM) networks we plan to model patient's diseases. Our approach will be transformative in providing critical decision support for patient care, enabling accurate understanding and evolution of diseases in patients.

Results and Accomplishments

We developed methods for embedding learning of medical concepts by using graph-based representation of SNOMED-CT, a widely popular knowledge graph in the healthcare domain with numerous operational and research applications. Our work included 1) Identification and extraction of medical concepts relevant to predictive learning on Electronic Healthcare Records(EHR), 2) Exploration of state of the art embedding learning methods, including Euclidean space methods such as (Node2vec and Metapath2vec) and hyperbolic space methods (Poincare) for embedding learning of the medical concepts using their graphical properties 3) Development of deep learning methods for integrating the medical concept representation into temporal patient state prediction models 4) An empirical analysis of various embedding methods, including the evaluation of their performance on multiple tasks of biomedical relevance (node classification, link prediction, and patient state prediction).

Our results show that concept embeddings derived from the SNOMED-CT knowledge graph significantly outperform state-of-the-art embeddings, showing 5-6x improvement in "concept similarity" and 6-20% improvement in patient diagnosis. The work was published in a KDD workshop (<u>https://arxiv.org/pdf/1907.08650.pdf</u>) and selected for spotlight presentation for Health day (<u>https://dshealthkdd.github.io/dshealth-2019/</u>). The code and the generated medical concept graph with embeddings was released as open source for use by the medical informatics community.(<u>https://gitlab.com/agarwal.khushbu/Snomed2Vec/-/tree/master</u>)

The project also led to sponsor funding from Veteran Affairs for development of predictive models for patient health (1.2M over 2 year to date) and setting up active collaborations with Stanford University, Center of population health sciences.
