Summary

The Hanford Site stores an estimated 56 million gallons of mixed radioactive and chemically hazardous waste in large underground tanks. In support of the Direct Feed Low-Activity Waste (DFLAW) program for expediting Hanford tank waste supernate treatment, laboratory-scale ion exchange processing using prototypic unit operations was conducted on AW-105 tank waste at the Pacific Northwest National Laboratory Radiochemical Processing Laboratory.

This report describes the batch contact testing for tanks AN-107 and AP-105 to help evaluate CST performance on tanks waste supernate after processing it in the ion exchange columns to strip ^{137}Cs. The volume of each supernate was adjusted to six Na concentrations (3.5 M, 4.5 M, 5.5 M, 6.0 M, 7.0 M, and 8.0 M Na) which were then spiked with ^{133}Cs at four concentrations (1.7E-04 M, 4.0E-04 M, 1.0E-03 M, and 1.7E-02 M Cs). Table S-1 provides a summary of the K_d and Q values for each tank waste matrix. All matrices showed a linear decrease in K_d with increasing Na concentration. The K_d and Q values for tanks AN-107 and AP-105 were compared to values from AP-107 results conducted in a separate study. Results from this work show slightly higher K_d values and significantly lower Q values than the AP-107 data.

1.0 Introduction

Hanford Tank Waste Operations and Closure (H2C) is the tank operations contactor for the U.S. Department of Energy (DOE) Hanford Field Office on the Hanford Site. The Hanford Site stores an estimated 56 million gallons of mixed radioactive and chemically hazardous waste in large underground tanks. In support of the Direct Feed Low-Activity Waste (DFLAW) Program, DOE deployed a strategy to pretreat supernate waste at tank farms and send it directly to Hanford's Waste Treatment and Immobilization Plant (WTP) Low-Activity Waste (LAW) facility for vitrification. To accommodate this strategy, DOE and H2C developed a two-phased approach. The first phase consisted of the deployment of a Tank Side Cesium Removal (TSCR) system located at AP Farm as a part of the TSCR Demonstration Project, which began operations in January 2022. This system provides the initial feed for hot commissioning of the WTP-LAW facility. The second phase will consist of the deployment of a higher capacity pretreatment system called the Advanced Modular Pretreatment System (AMPS) that can deliver sufficient feed for two melters in the WTP-LAW facility. Decanted tank waste supernate will be pretreated using AMPS to meet the WTP LAW Facility waste acceptance criteria (WAC). Specific to ^{137}Cs, this requirement is <3.18E-5 Ci ^{137}Cs/mole of Na.

The goal of this work was to test the effectiveness of CST to remove Cs from AN-107 and AP-105 supernate at six Na concentrations (3.5, 4.5, 5.5, 6.0, 7.0, and 8.0 M Na).

H2C funded PNNL to conduct testing with AP-105 tank waste under the Task 2 of the WRPS statement of work *FY 2022 Radioactive Waste Test Platform Testing*, Rev. 2, Requisition 351656, dated July 21, 2022. Testing with AN-107 tank waste was conducted under the WRPS statement of work *Tank 241-AN-107 Large Volume Sample Collection to Support Platform Testing, Phase 2, FY23*, Rev. 0, Requisition 366862, dated June 29, 2023. There are no deviations from the statement of work.

2.0 Quality Assurance

This work was conducted with funding from WRPS under requisition 366862: Tank 241-AN-107 Large Volume Sample Collection to Support Platform Testing, Phase 2, FY23. H2C funded PNNL to conduct testing with AP-105 tank waste under the Task 2 of the WRPS statement of work *FY 2022 Radioactive Waste Test Platform Testing*, Rev. 2, Requisition 351656, dated July 21, 2022. This work was performed in accordance with the Pacific Northwest National Laboratory (PNNL) Nuclear Quality Assurance Program (NQAP). The NQAP complies with the United States Department of Energy Order 414.1D, Quality Assurance, and 10 CFR 830, Subpart A, Quality Assurance Requirements. The NQAP uses NQA-1-2012, Quality Assurance Requirements for Nuclear Facility Applications, as its consensus standard and NQA-1-2012, Subpart 4.2.1, as the basis for its graded approach to quality. The data associated with this report was collected under technology readiness level (TRL) 5, the highest level of applied research under NQAP.

3.0 Test Conditions

This section describes the CST media, AN-107 tank waste, AP-105 tank waste, and batch contact conditions. All testing was conducted in accordance with a test plan prepared by PNNL and approved by the tank farm contractor.

3.1 CST media

The CST ion exchange media used in this study was procured by WRPS as ten 5-gallon buckets (149 kg total) of IONSIV R9140-B CST, Product 8056202-999, Lot No. 2002009604 from Honeywell UOP LLC (Des Plaines, IL, USA). Details of the procurement and material properties can be found elsewhere (Fiskum et al. 2019). The CST was sieved through a #30 sieve assembly and pretreated by contacting with 0.1 M NaOH to remove colloidal fines.

3.2 AN-107 Tank Waste Sample

The tank farm contractor collected multiple samples (36 at nominally 250 mL each) from the AN-107 Hanford tank in August and September of 2023. Characterization of the AN-107 samples are described elsewhere (Westesen et al. 2024). A source of ~5.5 M Na AN-107 was received for this study. The AN-107 source was separated into six aliquots for Na concentration adjustment. The aliquots were either diluted with DI water or heated to adjust the volume for the appropriate Na concentration for batch contact feed. The batch contact (BC) feed solutions were transferred into poly bottles to record gross mass. Sub-aliquots (2 mL) of each AN-107 BC feed were analyzed to determine ^{137}Cs content and Na concentration (ASR 2094).

3.3 AP-105 Tank Waste Sample

The tank farm contractor collected multiple samples (36 each at nominally 250 mL) from the AP-105 Hanford tank in October 2022. Characterization of the AP-105 samples are described elsewhere (Westesen et al. 2023). A source of ~5.5 M Na AP-105 was received for this study. The AP-105 source was separated into six aliquots for Na concentration adjustment. The aliquots were either diluted with DI water or heated to adjust the volume to achieve the appropriate Na concentration for batch contact feed. The BC feed solutions were transferred into poly bottles to

record gross mass. Sub-aliquots (2 mL) of each AP-105 feed were analyzed to determine ^{137}Cs content and Na concentration (ASR 2120).

3.4 Batch contact conditions

Batch contact experiments with AN-107 and AP-105 effluents were conducted to evaluate Cs loading at various Na concentrations. Stock solutions of 0.753 M (100 mg/mL) and 9.98E-02 M (13.3 mg/mL) $^{133}CsNO_3$ were prepared by dissolving the nitrate salt in a tared volumetric flask and diluted with DI water. Stocks of ^{133}Cs with known concentration and density were used for spiking of both AN-107 and AP-105 effluent samples. Four 50 mL centrifuge tubes were prepared for each BC feed solution to achieve 1.7E-04, 4.0E-04, 1.0E-03, and 1.7E-02 M Cs. The 0.084 M ^{133}Cs stock was spike in various volumes to 3 of the 4 centrifuge tubes per feed solution. The fourth centrifuge tube was spiked with the 0.753 M ^{133}Cs stock. A 30 mL aliquot of each feed solution was added to its appropriate 50 mL centrifuge tube. The solutions were prepared gravimetrically, and exact volumes were calculated from mass and density measurements.

A nominal 0.075 g (dry mass basis) aliquot of CST was measured into 20 mL vials and used to determine the dry mass of the exchanger. The F-factor was measured at nominally 105 °C with a value of 0.4262 for AN-107 and 0.3737 for AP-105 BC testing, respectively. The lower-than-expected F-factor is likely due to the CST not being fully dry before F-factor testing. This F-factor was used to calculate the target mass of CST for the batch contact tests. F-factor samples were again collected in duplicate, bracketing batch contact sample collection. The average F-factor was measured at 105 °C with an average value of 0.5404 for AN-107 and 0.5181 for the AP-105 BC testing, respectively. These values were used to measure the dry mass of CST for their respective tank waste samples.

Aliquots (15 mL) of the BC feed solutions were added to the appropriate vials (in duplicate); the exact volume transferred was calculated from net solution mass and density. The solution-to-mass phase ratio was averaged 193 ± 4 and 141 ± 1 for AN-107 and AP-105, respectively.

Batch contact tests were conducted subsequently; first the AN-107 then with AP-105. All samples were contacted at ambient temperature on a large orbital shaker set to 200 RPM. The temperature was monitored using a vial of DI water co-located with each sample set.

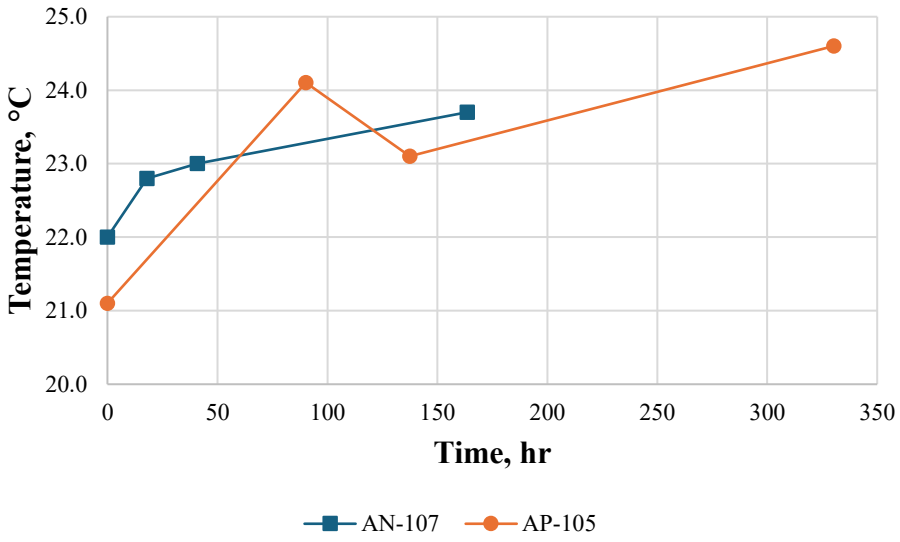

Figure 3-1. Temperature profile of batch contact testing with AN-107 and AP-105 tank waste supernate.

After contact, 2 mL of the supernate was removed and filtered through a 0.45 µm pore size nylon syringe filter and transferred to a glass vial for gamma energy analysis (GEA). The ^{137}Cs activity measured by GEA in pre- and post-contacted solutions was used to determine the total Cs exchange. Analysis and data reduction were conducted using the methods previously reported (Fiskum et al. 2019a). The isotherm data were fitted to a Freundlich/Langmuir hybrid equilibrium fit (Hamm et al. 2002).

The batch distribution coefficients were calculated according to Eq. (3.1).

$$\frac{(A_0 - A_1)}{A_1} \times \frac{V}{M \times F} = K_d \qquad 3.1$$

where A_0 = initial 137Cs concentration (µCi/mL)
A_1 = final (equilibrium) ^{137}Cs concentration (µCi/mL)
V = volume of the batch contact liquid (mL)
M = measured mass of CST (g)
F = F-factor, mass of the 105 °C dried CST divided by the mass of the undried CST
K_d = batch-distribution coefficient (mL/g)

Final (equilibrium) Cs concentrations (C_{Eq}) were calculated relative to the tracer removed in the contacted samples (A_1/A_0) and the initial Cs concentration (C_0) according to Eq. (3.2).

$$C_0 \times \left(\frac{A_1}{A_0}\right) = C_{Eq} \qquad 3.2$$

where C_0 = initial Cs concentration in solution (µg/mL or M)
C_{Eq} = equilibrium Cs concentration in solution (µg/mL or M)

The equilibrium Cs concentrations loaded on to the CST (Q in units of mmoles Cs per gram of dry CST mass) were calculated according to Eq. (3.3).

$$\frac{C_0 \times V \times \left(1 - \frac{A_1}{A_0}\right)}{M \times F \times 1000 \times FW} = Q \qquad 3.3$$

Where Q = equilibrium Cs concentration in the CST (mmole/g CST)
1000 = conversion factor to convert µg to mg
FW = Cs formula weight

3.5 Sample analysis

Cesium load performance was determined from the ^{137}Cs measured in the collected samples relative to the native ^{137}Cs in each respective feed. The samples collected were analyzed directly to determine the ^{137}Cs concentration using GEA.

The ASO was responsible for the preparation and analysis of appropriate analytical batch and instrument quality control samples and for providing any additional processing to the sub-samples that might be required (e.g. acid digestion, radiochemical separations, dilutions). All analyses were conducted by the ASO according to their standard operating procedures, the ASO AQ Plan, and the Analytical Service Request (ASR). Samples were analyzed directly (no preparation) by GEA.

4.0 Results

This section discusses the Cs exchange behavior during batch contact testing with variable Na AN-107 and AP-105 tank waste. Batch contact raw data are provided in Appendix A.

4.1 K_d and isotherm results

Figure 4-1 shows the K_d dependence on Cs concentration in AN-107 at various Na concentrations. The K_d increased with decreasing Na concentration. This result is expected as Na competes directly with Cs for CST sites (Campbell 2023). The data show negligible changes in the K_d for the three lower Cs concentrations (1.7E-04 M, 4.4E-04 M, and 1.0E-03 M) measured. This behavior has been observed for AP-105 (Westesen 2023) and suggests that there is no impact on K_d with small changes in Cs concentrations of <1E-03 M Cs. For the lower Cs concentration samples at 6.0 M Na, there is a significant change in K_d between the duplicate measurements. Also at the lower Cs concentrations, the 7.0 M Na samples show a slightly lower K_d than the 8.0 M Na samples. These results are likely just associated with analytical uncertainty in the K_d measurements and should not be taken as a significant deviation. Rather, trends should be assessed across the entirety of the data set to evaluate the impact of changing Na concentrations on CST performance.

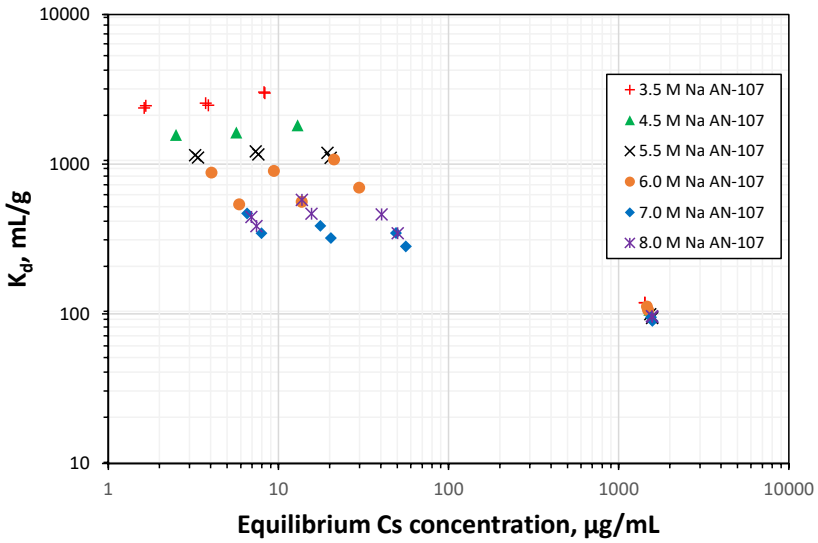

Figure 4-1. Cs K_d vs Cs concentration, AN-107 at six Na concentrations.

Figure 4-2 shows the K_d dependence on Cs concentration in AP-105 at various Na concentrations. Similar to the AN-107 batch contact study, the K_d is shown to increase with decreasing Na concentration and minimal changes to the K_d were seen as the Cs concentration varied between the three lowest conditions. At the higher Cs concentration, there is little change to the K_d at all Na concentrations.

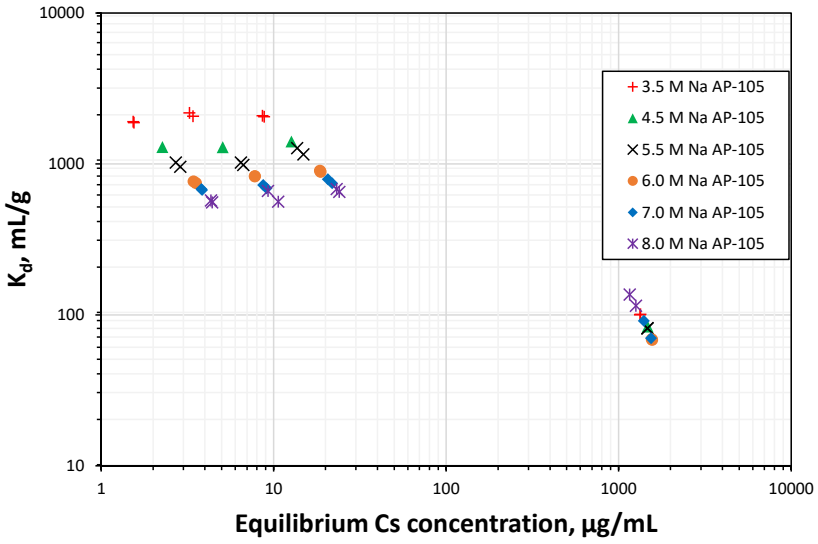

Figure 4-2. Cs K_d vs Cs concentration, AP-105 at six Na concentrations.

Figure 4-3 and Figure 4-4 show the impact of Na concentration on K_d in AN-107 and AP-105, respectively. At the lower Cs concentrations, the K_d shows a steady decrease with increasing Na concentration.

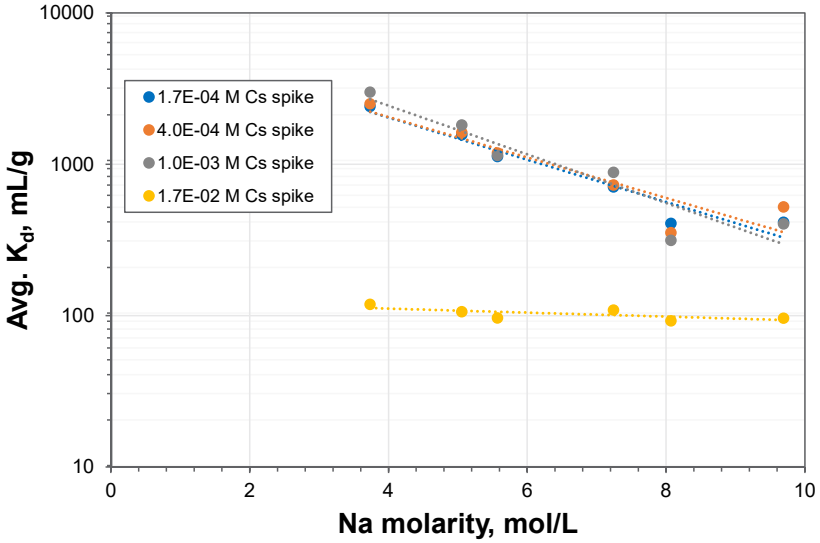

Figure 4-3. Average K_d vs Na concentration, AN-107 at four Cs concentrations.

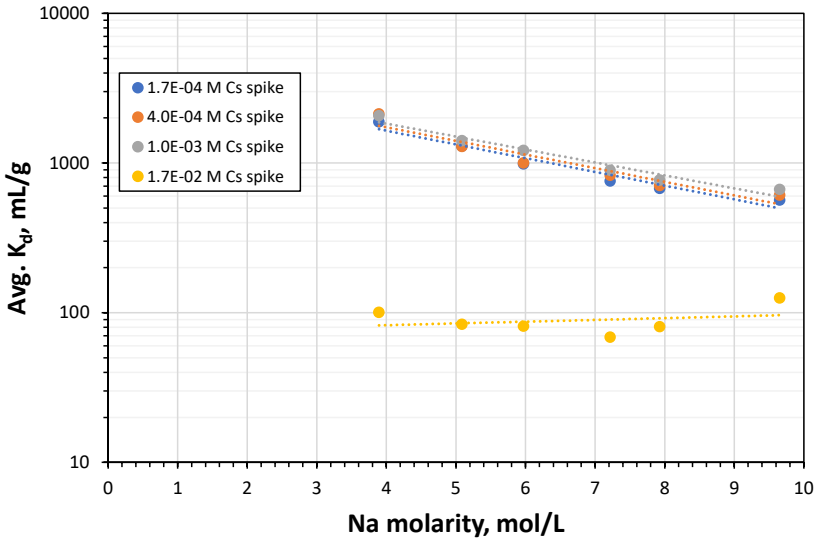

Figure 4-4. Average K_d vs Na concentration, AN-107 at four Cs concentrations.

Figure 4-5 and Figure 4-6 show corresponding isotherms and Q (mmoles Cs/g dry CST) values against Cs molarity at all Na concentrations for AN-107 and AP-105 tank waste, respectively. For this model, the α_i (total capacity in the matrix) was set to 0.68 mmoles Cs/g CST for this evolution of testing. Also provided are the curve fits to the Freundlich/Langmuir hybrid equilibrium model as given in Eq. 4.1.

$$Q = \frac{\alpha_i \times [Cs]}{(\beta + [Cs])} \qquad 4.1$$

where [Cs] = equilibrium Cs concentration, mmoles/mL or M
Q = equilibrium Cs loading on the CST, mmole Cs per g CST
αi = isotherm parameter constant (mmoles/g), equivalent to total capacity in the matrix
β = isotherm parameter constant (mmoles/mL or M), selectivity coefficient, dependent on matrix and temperature; the larger the value, the less selective the CST is for Cs

The results for both tanks show a decreasing trend in Cs loadings (Q values) with increasing Na concentrations. This can be attributed reduced ionic strength and decreased competitive ion effects as a result of sample dilution. For the AN-107 tank, the 7.0 M Na model shows lower Cs loadings than the 8.0 M Na model. This is consistent with the K_d values recorded; the trend is attributed to analytical uncertainty and considered negligible.

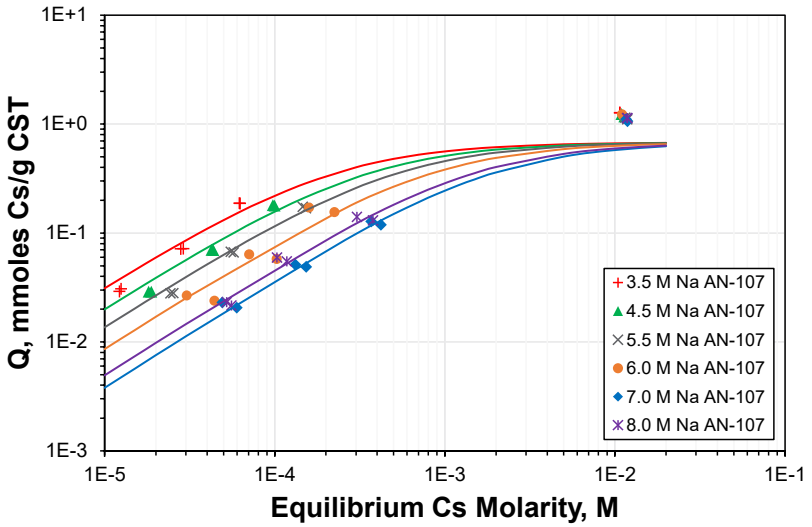

Figure 4-5. Q vs equilibrium Cs concentration for AN-107 tank waste with Freundlich/Langmuir hybrid equilibrium fits at various Na concentrations.

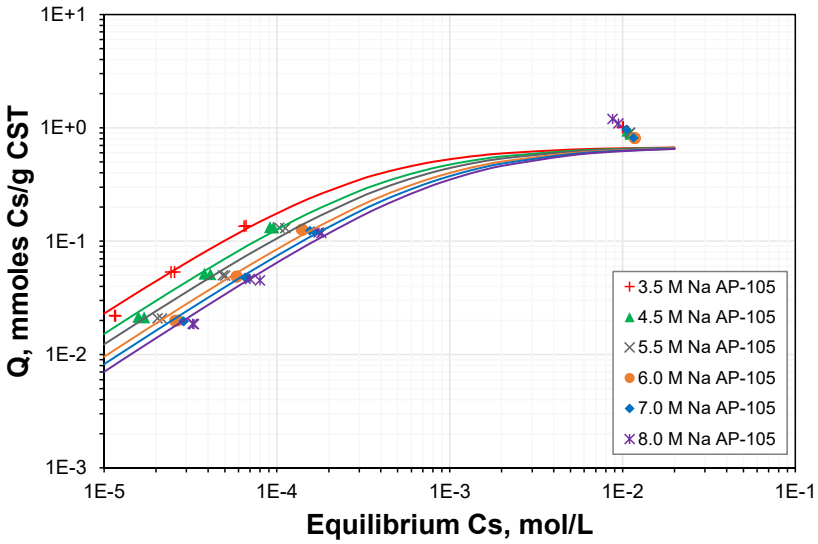

Figure 4-6. Q vs equilibrium Cs concentration for AP-105 tank waste with Freundlich/Langmuir hybrid equilibrium fits at various Na concentrations.

4.2 Tank waste comparisons

Batch contact studies were conducted on AN-107 and AP-105 (this work) and AP-107 (Campbell 2023) to assess Cs removal at variable Na concentrations. Table 4-1 shows a comparison of the K_d and Q values for CST in the three tank samples; data is normalized to Na concentrations in AN-107. For all tank wastes, both K_d and Q values show a general decreasing trend with increasing Na concentration as expected with increasing ionic strength. The AN-107 data show higher K_d values than either AP-105 or AP-107. This is due to the lower potassium concentration in this sample. The data for AP-107 and AP-105 overlap – indicating that there are nominal separations between these two tanks. Prior column testing has demonstrated that CST has a

slightly greater capacity for cesium in the AP-107 matrix (implying slightly higher K_d values), but this is difference is difficult to assess solely from batch contact tests. It is interesting to note that the AN-107 sample shows a much greater dependence on sodium loading. The cesium loading varies by more than a factor of 2 between 3.5 M and 8 M. This is assessed by multiplying the sodium molarity by the K_d. In contrast, AP-105 and AP-107 showed roughly a 30% decrease in cesium capacity. Again, this is likely associated with the much lower potassium content in the AN-107 sample but should be validated with other low potassium matrices. These changes are due to the changes in activity coefficients as a function of the ionic strength of the solution (as a result of dilution) and the mix of anions that are present. Prior work has shown that the cesium activity coefficient is impacted more by increases in ionic strength than the sodium activity coefficient. This non-ideality results in lower effective cesium loading at higher ionic strength.

5.0 Conclusions

A comparative analysis of batch contact testing was conducted for AN-107 and AP-105 samples at various Na and Cs concentrations. Batch contacts were conducted in duplicate with 0.075 g dry CST (Lot No. 2002009604) per 15 mL of solution and agitated at ambient temperature for an average of ~240 hours. The isotherm data were fit to the Freundlich/Langmuir hybrid equilibrium model to calculate K_d and Q values. These results were compared to AP-107 data. The following conclusions were made from this testing:

1. For all tank wastes, the data suggests CST's selectivity and capacity for Cs removal are more pronounced in scenarios with lower Na concentrations; this is influenced by the overall lower ionic strength of the tank waste samples and the impact on activity coefficients associated with these changes in ionic strength.

2. All tank wastes exhibited decreasing K_d values with increasing Na concentration, indicating the influence of competitive ion presence on the CST's affinity for Cs.

3. AN-107 showed generally higher K_d and Q values across all tested Na concentrations compared to AP-105. The differences are primarily due to the lower potassium in AN-107.

4. AP-105 and AP-107 showed similar K_d values, however prior column testing has demonstrated that CST has a slightly higher affinity for cesium in the AP-107 matrix.
