

Green Hornet: Visual Analytics for Large Graphs

Patrick Mackey, Nicholas Cramer,
Dave Gillen, Doug Love, Liz Faultersack

What is Green Hornet?

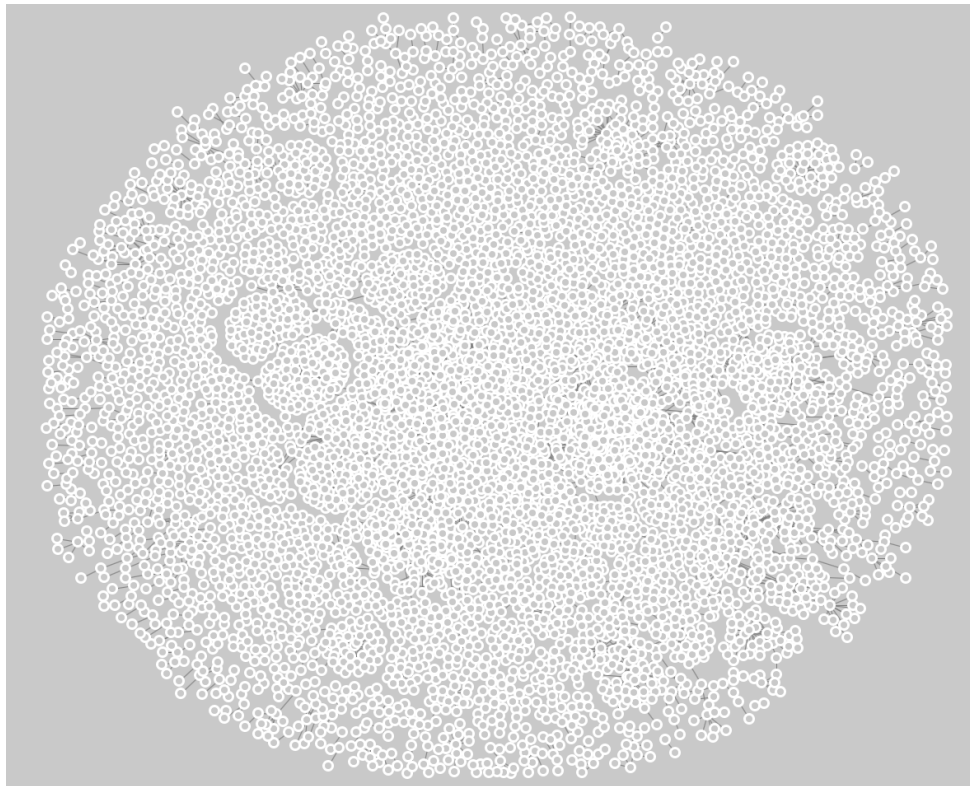

- Green Hornet is a graph visual analytics tool for enabling analysts to explore graphs with up to **1 million** nodes and edges.
- It was designed to be a powerful graph analytics tool *without* requiring expertise in mathematics or data science.
- It makes such large graphs understandable through use of “supernodes”.

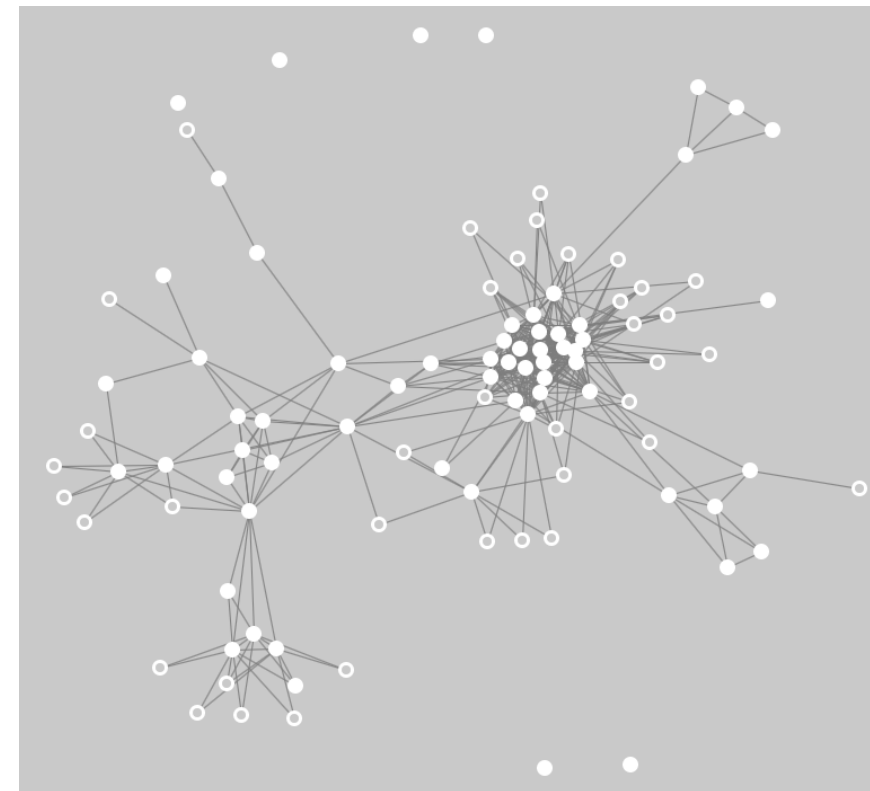

Supernode Based Approach

- Large graphs quickly become “hairballs” as the number of nodes and links increases
- Green Hornet uses **supernodes** to cluster groups of nodes
- The resulting graph has much less clutter, and enables users to see the underlying structure better

Full Graph

Supernodes

The same graph, before and after clustering.

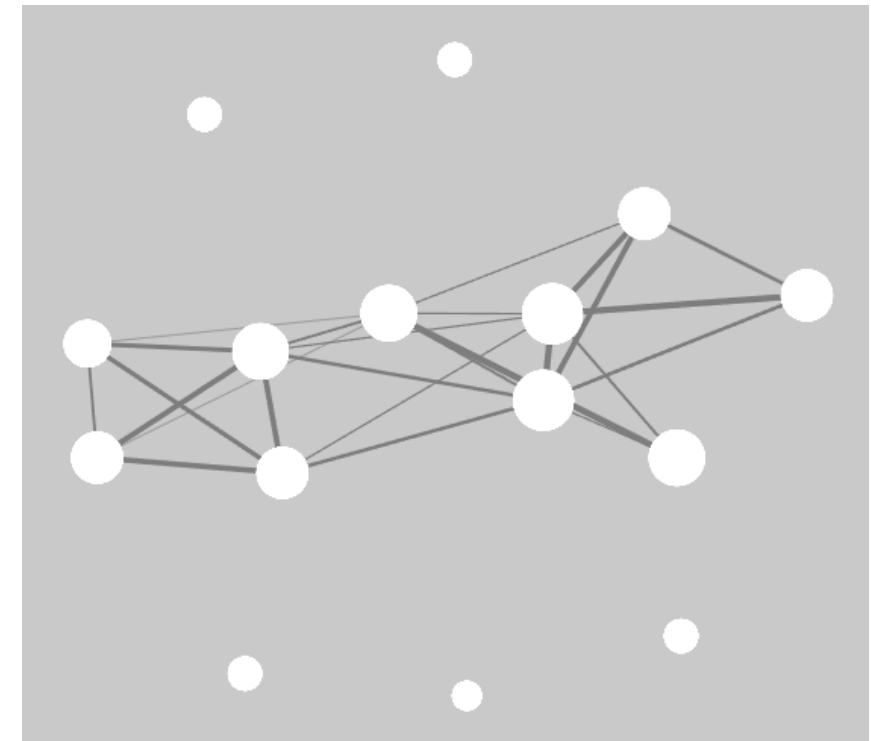

The structure becomes much more apparent with the use of supernodes.

Graph size: 6,396 nodes, 9,368 links

Clustering Options

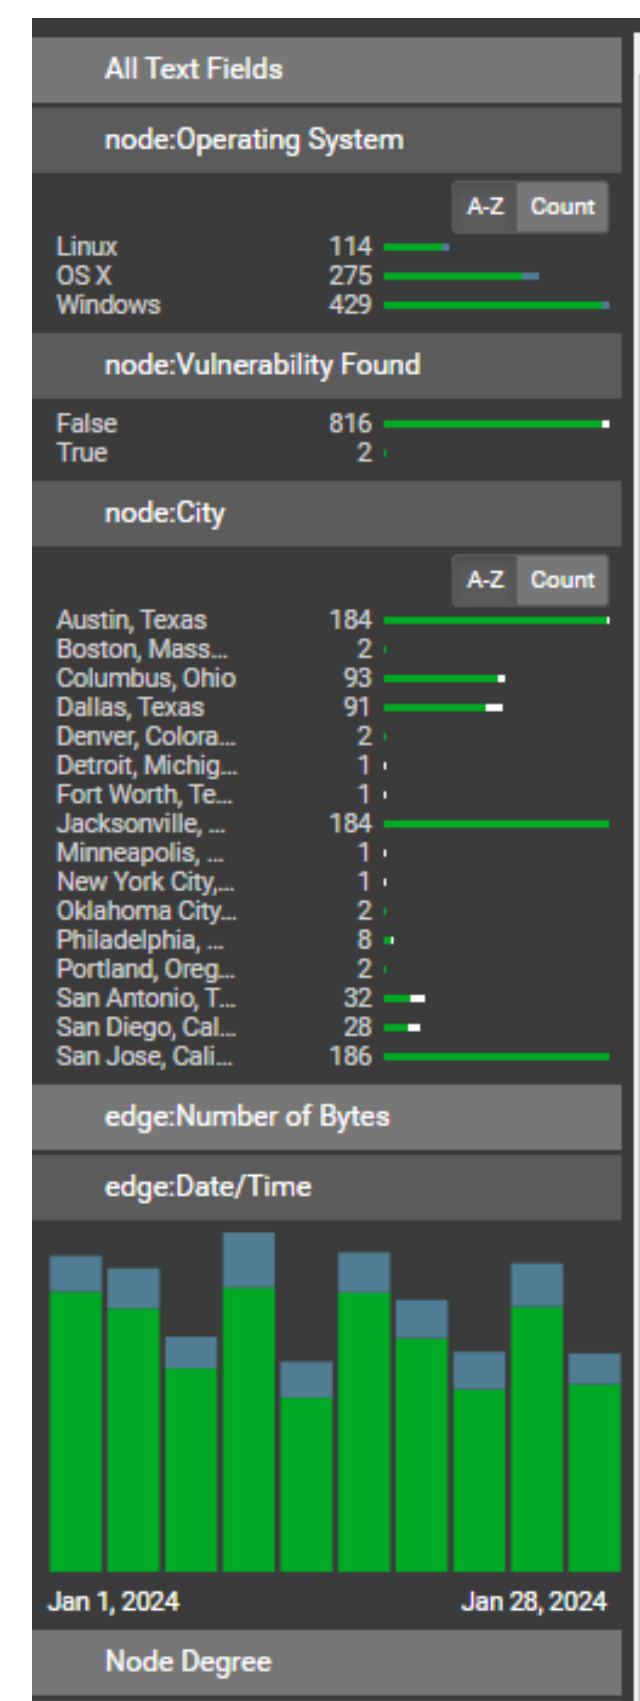

Different options are available for clustering, including:

- Louvain community detection
 - Clusters nodes that are more connected to each other than the rest of the graph (e.g., tightly connected network resources)
- Structural equivalence
 - All nodes that share the same neighbors become clustered together (e.g., all accounts that interact with the same IP addresses)
- Node property-based approach
 - Any user-defined node property can be used to create the clusters (e.g., city associated with an IP address)
- Manually – via lassoing groups of nodes together
 - Allows users to create supernodes interactively as needed

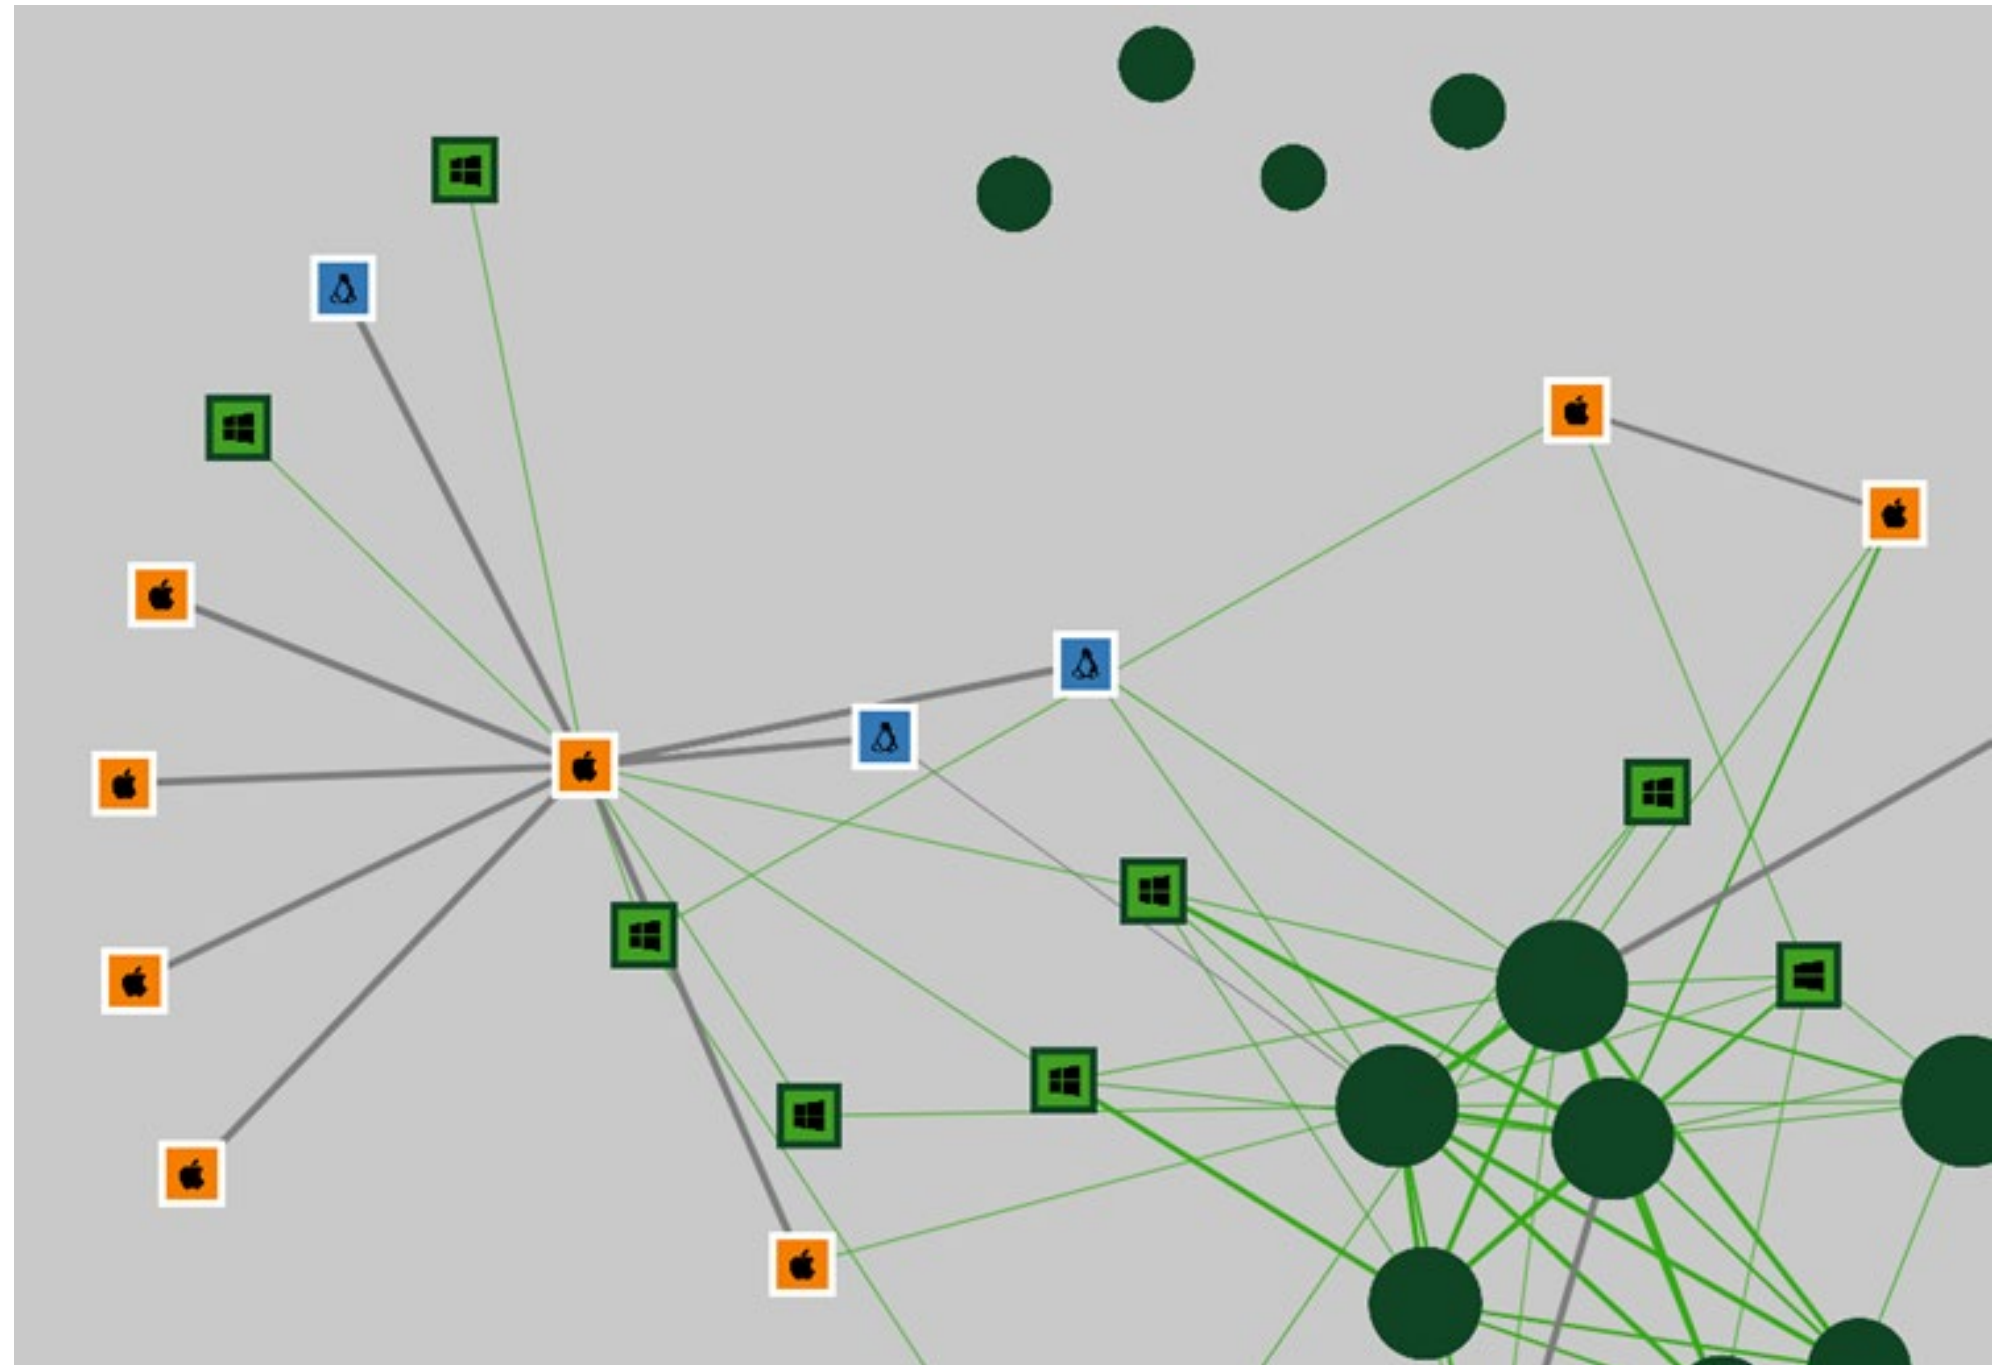

Node and Edge Properties

- Green Hornet is specifically designed to work for **property graphs**
- Many kinds of properties can be represented on nodes or edges:
 - Free text (e.g., error message additional details)
 - Categorical text (e.g., operating system, device browser)
 - Integers (e.g., number of log-in attempts, port address)
 - Floating point (e.g., importance scores, edge weights)
 - Booleans (e.g., true or false status)
 - IP addresses (including CIDR search capability)
 - Date/time
- Search capabilities provided for all properties
- Includes summary of graph properties
 - Available for whole graph or sub-selection

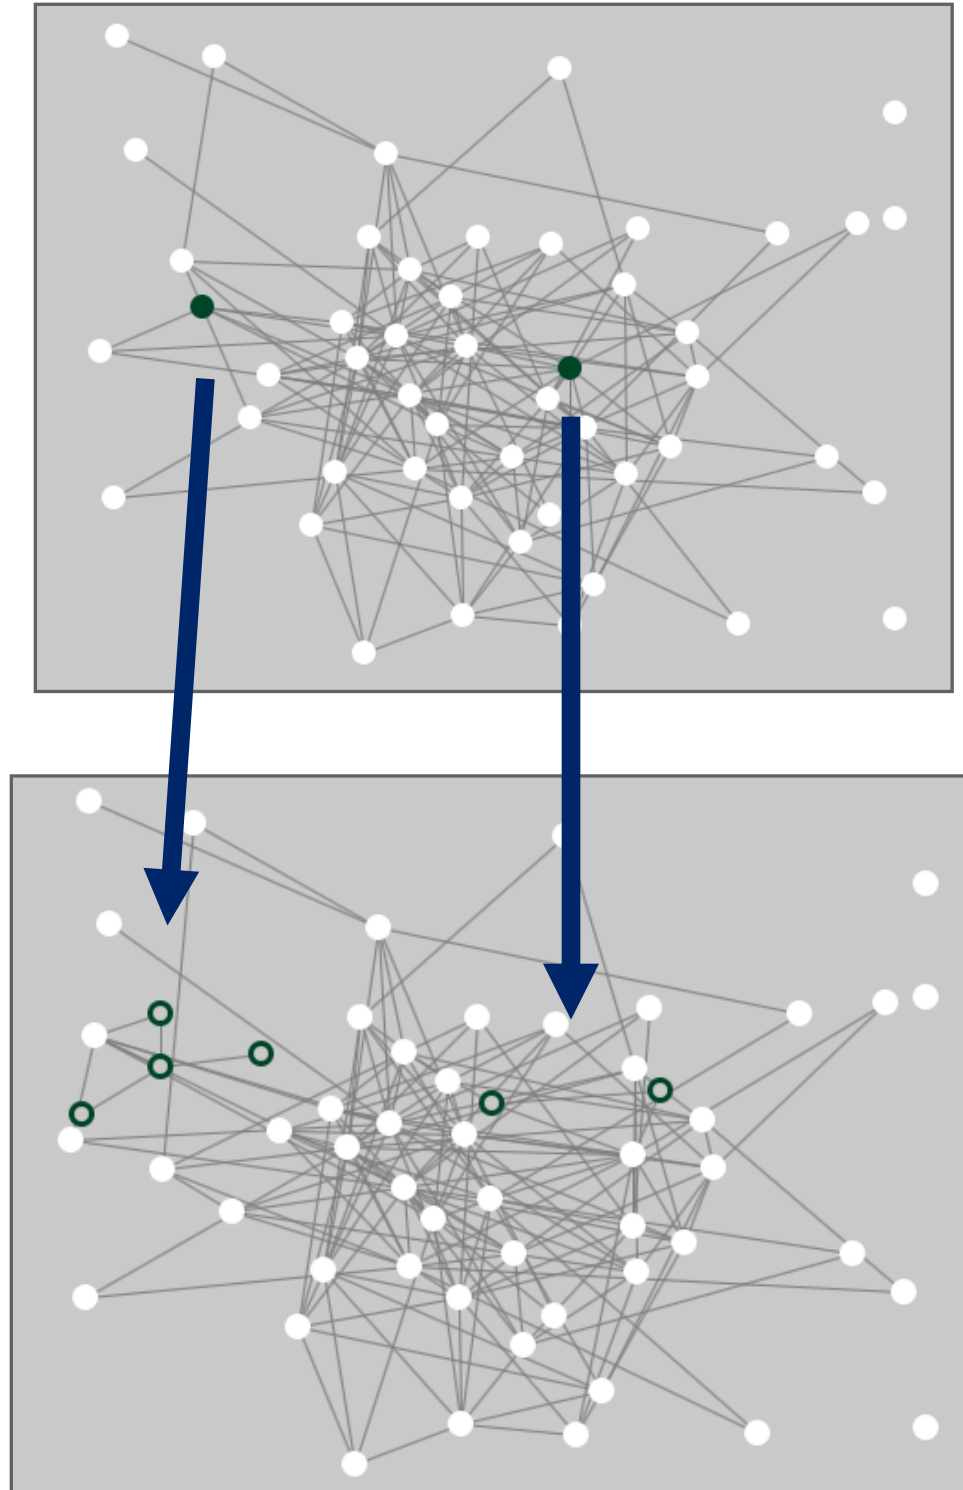

Iconography

- Node type and properties can be represented through use of **color** and **icons**.
- These can be **customized** by the user to more intuitively represent important concepts in their data.

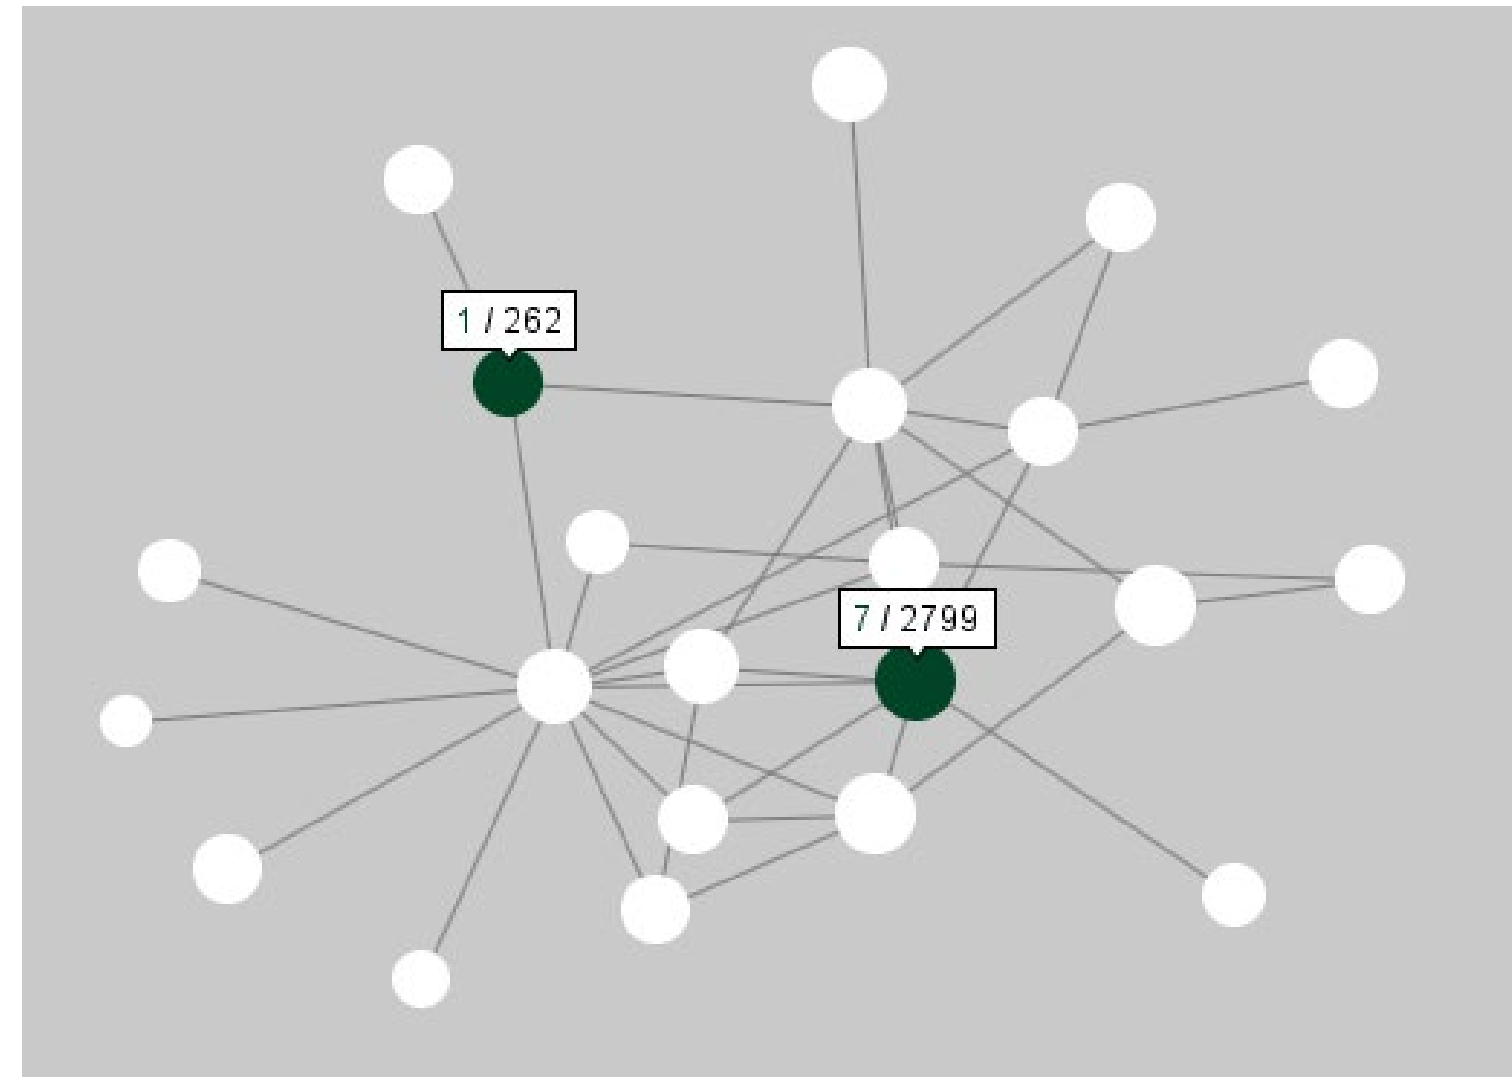

Interactive Exploration

- While supernodes allow you to see the high-level structure, users also want to investigate specific nodes and edges.
- This is typically done via a process of:
 - **Selection** (either manually, or by searching for specific node/edge properties, or other graph characteristics)
 - **Expansion** of specific nodes from their supernodes
- The goal is to enable users to simultaneously zoom-in to nodes of interest while maintaining high-level global view of the graph.

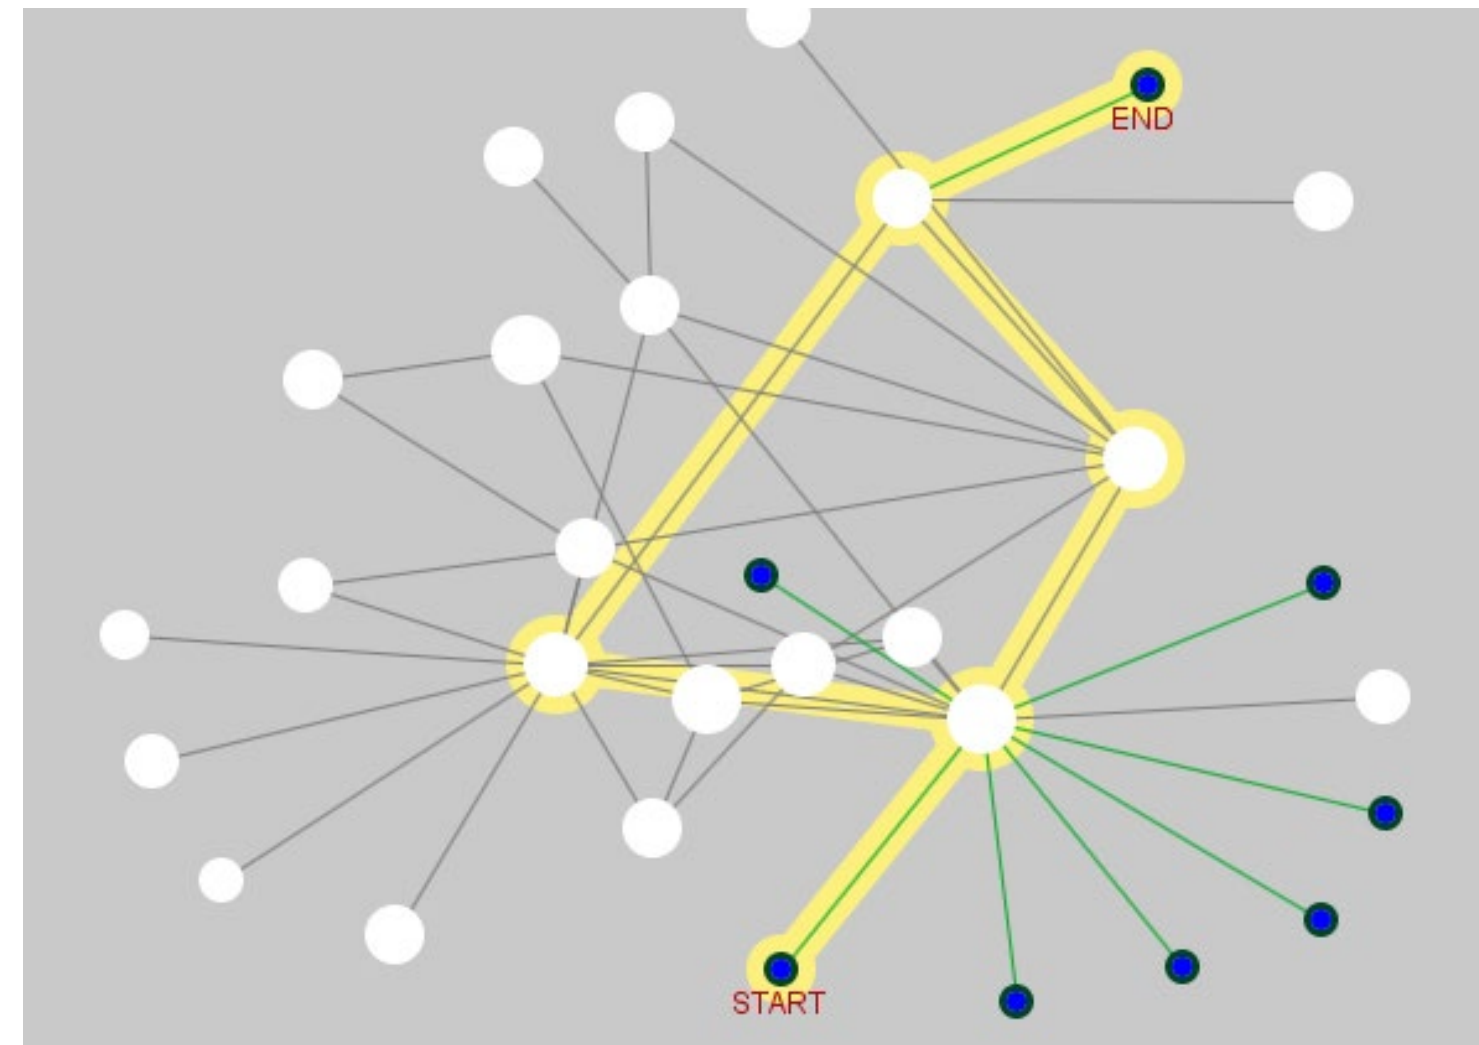

Graph Selection

- Node/edge selection is one of the primary ways users explore a graph
- Selections are made in one of the following ways:
 - Searching by node/link properties
 - Manual selection of nodes/links
 - Searching by graph patterns like shortest path
- Any supernode with at least one individual node/link is considered “selected” and shown in green
- Many of the features for graph exploration and visualization are based around which nodes and links you currently have selected
- Supernode labels show the number of selected nodes as well as the total number of nodes

Highlighted Nodes/Links

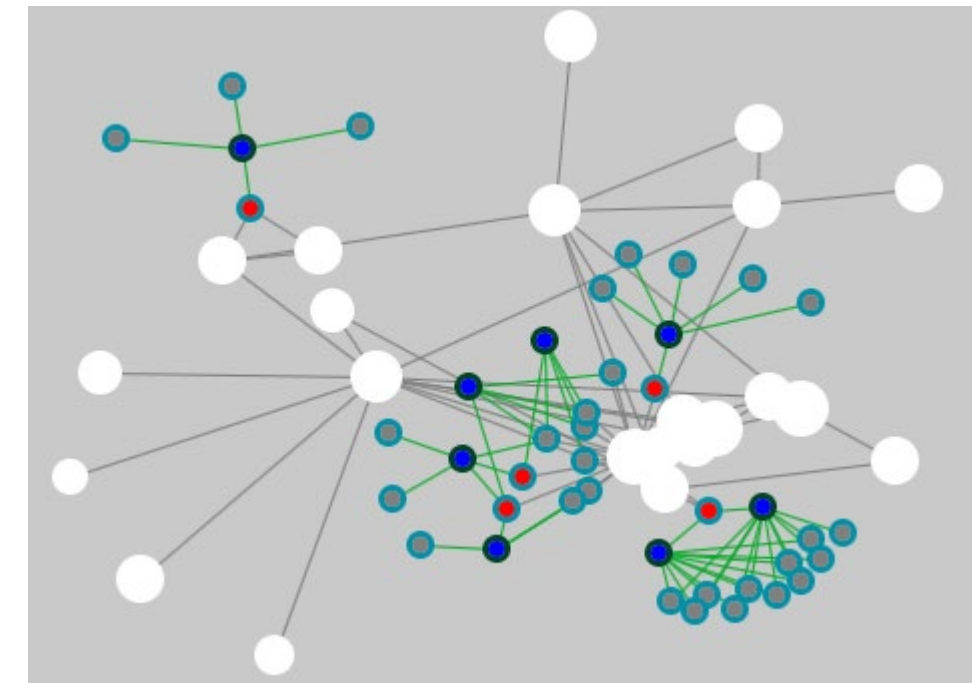

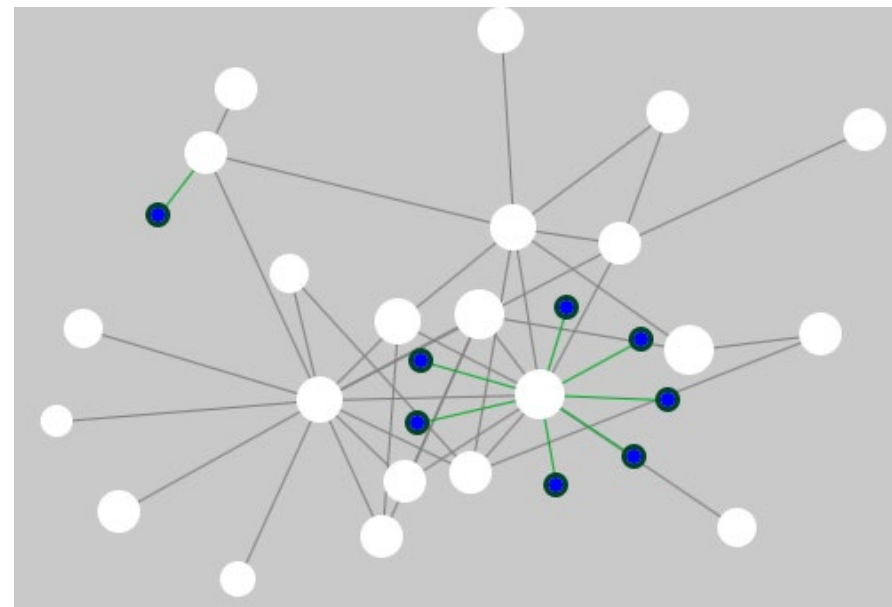

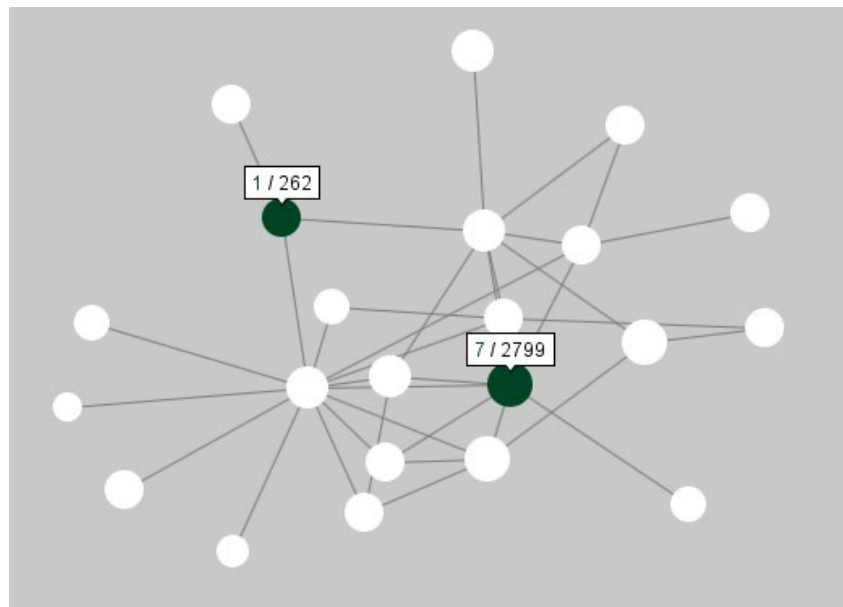

- In addition to the “selection”, users can also highlight nodes/links of interest
- This is primarily done through graph algorithms like:
 - Shortest paths
 - k-cores
 - Vertex similarity
- It can also be done through node and link properties
- Highlighted nodes/links are marked in yellow
- Highlighted nodes/links can be converted into the selection

Expanding Nodes of Interest

- Both selected and highlighted nodes can be extracted from their supernodes
- This allows the user to see individual nodes of interest while keeping the rest of the graph clustered
- The neighbors of the selection/highlight can also be expanded up to 5 hops away

List Panel (Spreadsheet View)

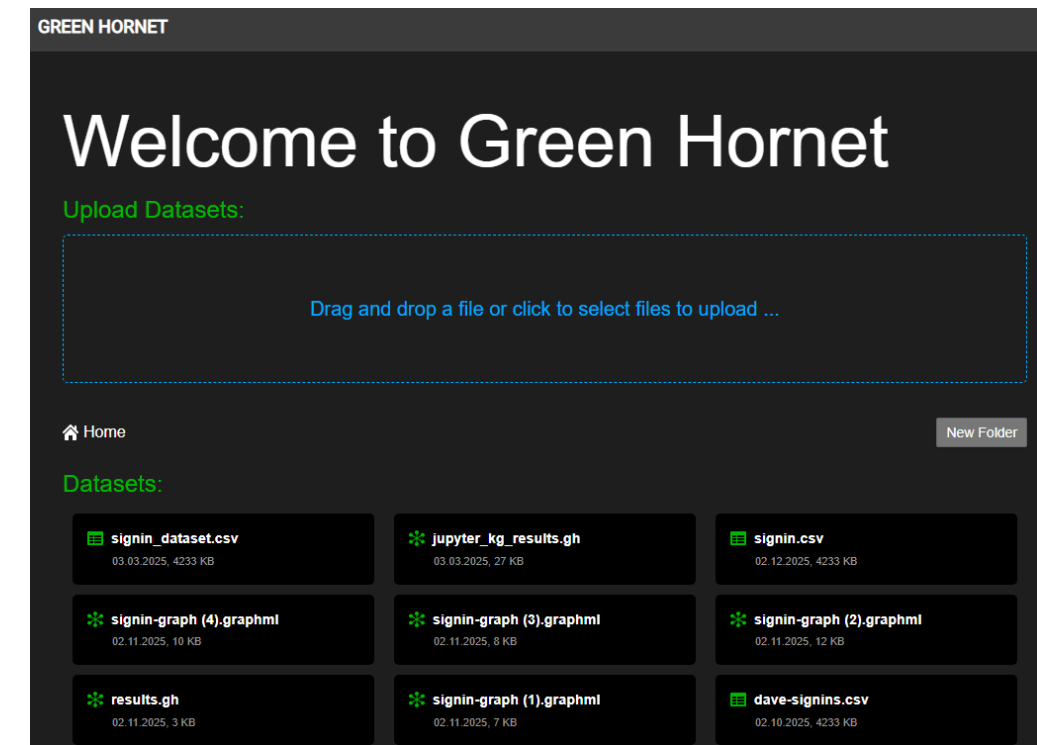

- Users can view the raw data related to nodes/edges and their properties
- This reflects the current selection and expansion
- Clicking on rows highlights the specific nodes/links representing the data
- Selections can be exported for use in other tools / reports

Data Formats

Green Hornet supports the following file formats:

- GDF files:
 - An extension of CSV data specifically for graphs
- GraphML
 - A common standard for graph modeling
- Green Hornet's proprietary *.gh format
 - Enables specialized Green Hornet features
- CSV files
 - Any CSV can be loaded as a graph
 - Includes special graph modeling capabilities, enabling users to interactively re-define how the CSV represents the graph

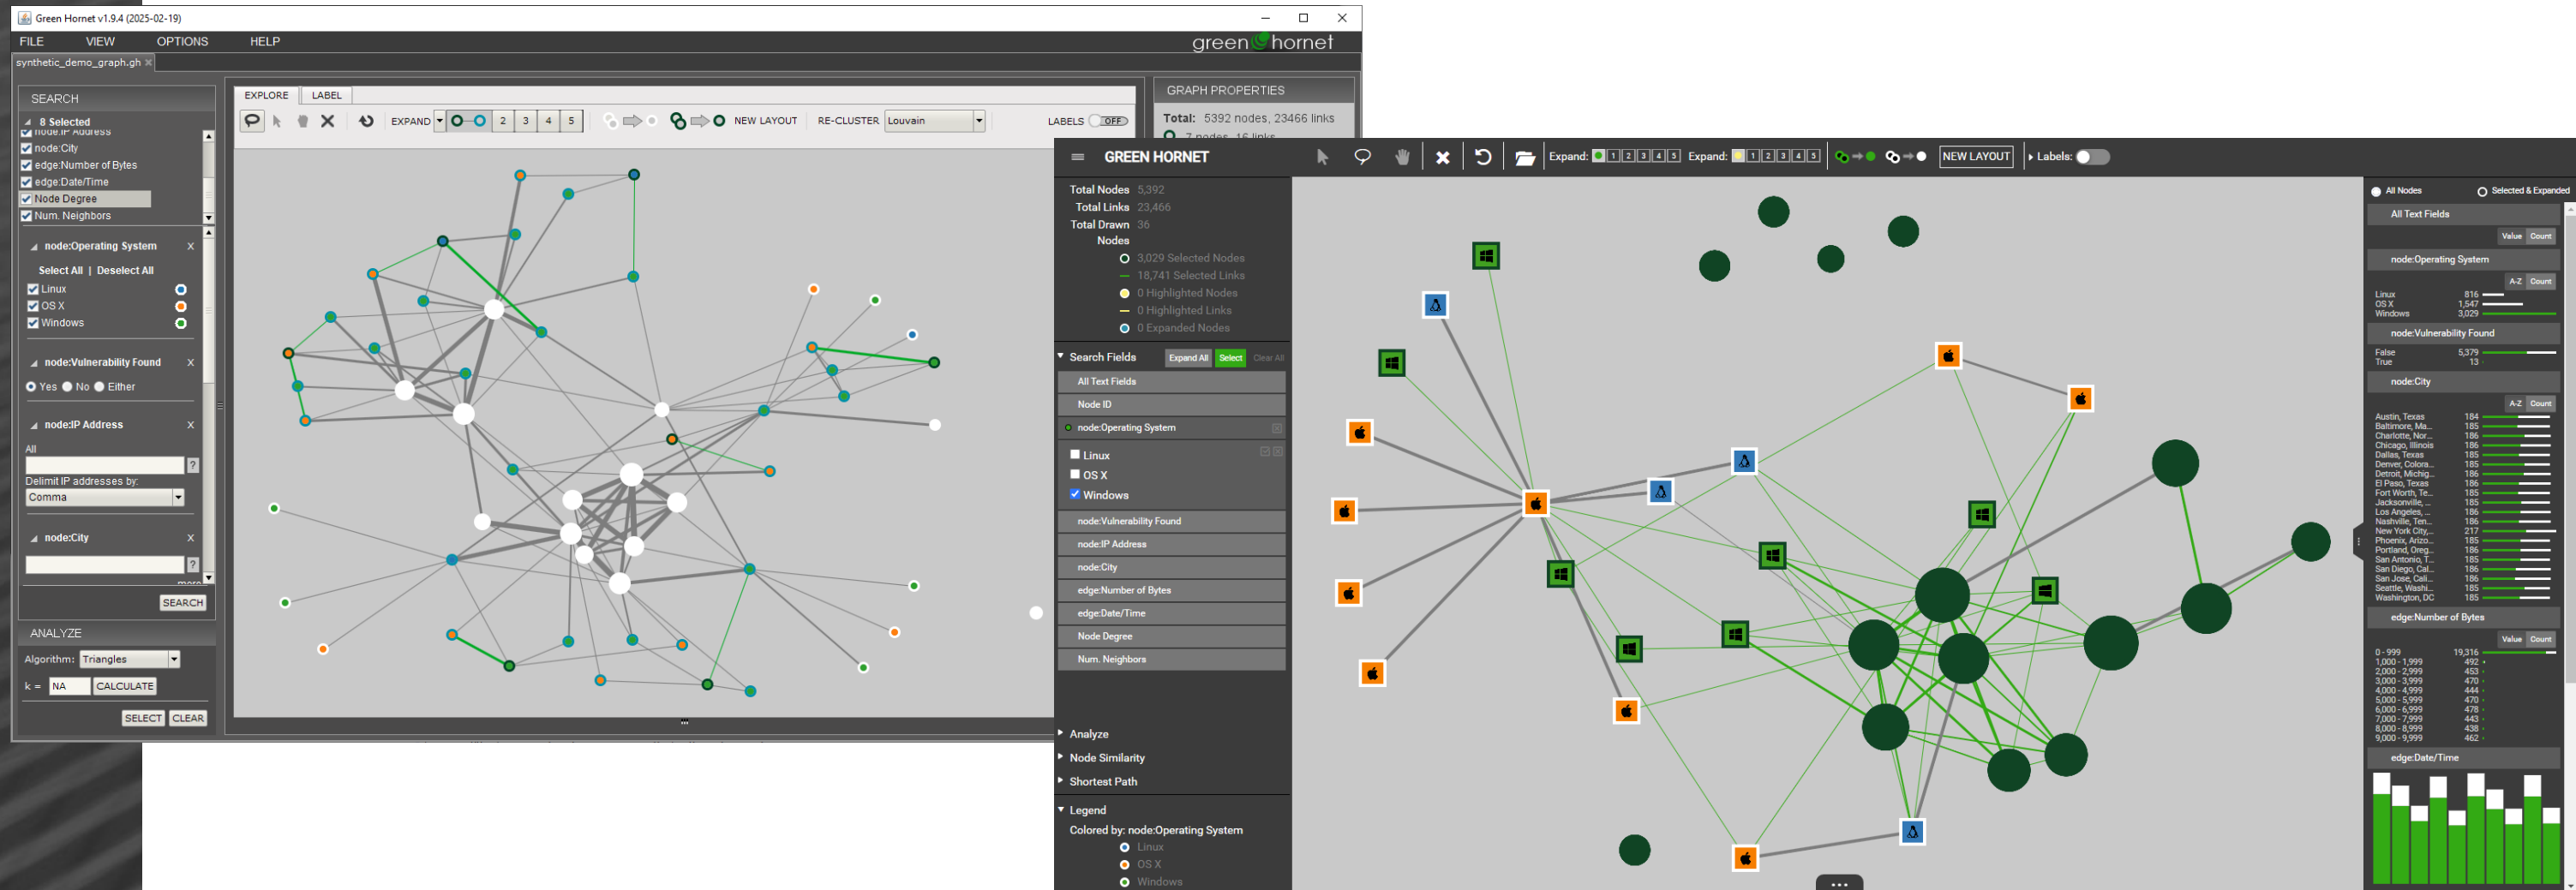

Integrated Graph Modeling

- Any pair of columns can be selected as the source and destination, for example:
 - **User Account to Error Message**
 - **IP Address to Role**
 - Etc.
- Users can interactively change the columns to create different “**perspectives**” into the same data
- The graph **selection** persists during changes
 - Enables users to see how the same data looks from different graph “perspectives”
 - For example, different types of relationships associated with a particular error message

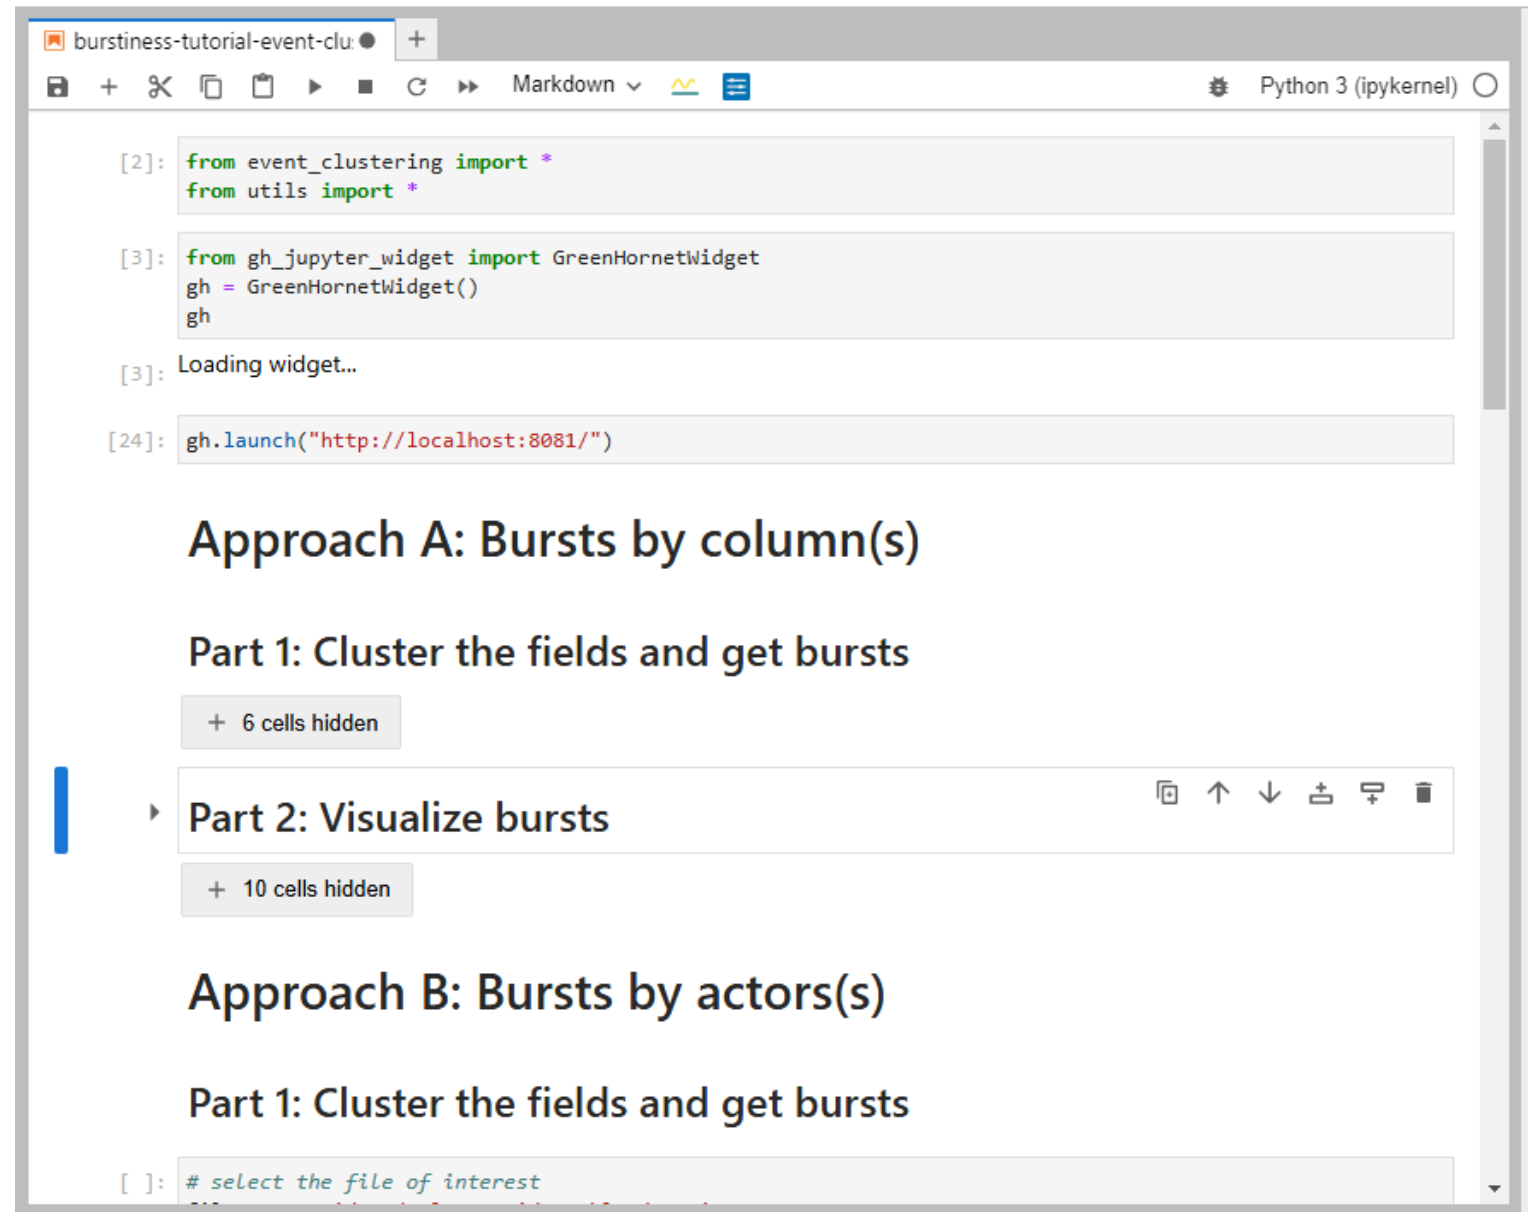

Desktop and Web Based Options

Both pure desktop and thin-client web-based versions available for deployment

Jupyter Notebook Integration

- Green Hornet Web also supports **Jupyter Notebook** integration
- Notebooks can be used to:
 - Create graphs
 - Modify an existing dataset
 - Perform graph analytics
 - Machine learning
- Results can be viewed automatically in Green Hornet
- Green Hornet data and interactions (e.g., selection and highlight) can be loaded into your notebook

The screenshot shows a Jupyter Notebook window titled "burstiness-tutorial-event-clu". The interface includes a toolbar with icons for file operations, a "Markdown" dropdown, and a "Python 3 (ipykernel)" environment selector. The notebook contains several code cells:

```
[2]: from event_clustering import *
     from utils import *

[3]: from gh_jupyter_widget import GreenHornetWidget
     gh = GreenHornetWidget()
     gh

[3]: Loading widget...

[24]: gh.launch("http://localhost:8081/")
```

Below the code cells, the notebook displays a table of contents with expandable sections:

- Approach A: Bursts by column(s)**
 - Part 1: Cluster the fields and get bursts
 - + 6 cells hidden
 - Part 2: Visualize bursts
 - + 10 cells hidden
- Approach B: Bursts by actors(s)**
 - Part 1: Cluster the fields and get bursts

At the bottom, a code cell is partially visible with the comment: `[]: # select the file of interest`.

Thank you
