Chapter 7

High-Resolution Characterization of the Shallow Unconsolidated Subsurface Using Direct Push, Nuclear Magnetic Resonance, and Groundwater Tracing Technologies

Gaisheng Liu, John F. Devlin, Peter Dietrich, and James J. Butler Jr.

Abstract Groundwater protection and contaminated site remediation efforts continue to be hampered by the difficulty in characterizing physical properties in the subsurface at a resolution that is sufficiently high for practical investigations. For example, conventional well-based field methods, such as pumping tests, have proven to be of limited effectiveness for obtaining information, such as the transmissive and storage characteristics of a formation and the rate at which groundwater flows, across different layers in a heterogeneous aquifer system. In this chapter, we describe a series of developments that are intended to improve our discipline's capability for high-resolution characterization of subsurface conditions in shallow, unconsolidated settings. These developments include high-resolution methods for hydraulic conductivity (K) characterization based on direct push (DP) technology (e.g., DP electrical conductivity probe, DP permeameter, DP injection logger, Hydraulic Profiling Tool (HPT), and High-Resolution K tool), K and porosity characterization by nuclear magnetic resonance (NMR), and groundwater flux characterization by monitoring the movement of thermal or chemical tracers through distributed temperature sensing

Why not conventional single-interval monitoring wells?

Engineered multilevel monitoring systems prevent ambient vertical flow in the boreholes and provide samples from multiple depths

Inflatable straddle packer systems

Home Packers

Inflatable Packers

A packer is an expandable plug used to isolate sections in a well for flow control, testing, and sampling.

The inflatable packer has significant **advantages** compared to other types of packers.

- **High pressure rating** and expansion ratio.
- **Minimal outside diameter** and large interior diameter.
- **Long sealing section** that conforms to uneven sides of the wellbore.

Our patented packers are available for:

- Borehole sizes ranging from **2" to 30"** (50 to 760 mm)
- Pressure ranges from **50 to 10,000 psi** (3 to 700 bar)

Furthermore, we provide our customers with a wide selection of **designed** packer assemblies for unique applications.

For more general information about packers, please visit our website.

So that we can better understand your application, please download the pdf files.

The resonant sonic drilling method offers unique capabilities to the environmental restoration market. By using a drill head that imparts high-frequency, high-force vibrations into a steel drill pipe, continuous, relatively undisturbed

The field of environmental contamination assessment and cleanup has become a multibillion dollar market in the United States over the last decade. Given the magnitude of the dollars that still need to be spent on these problems in the future, there has been a strong desire by most governmental agencies and potentially responsible parties involved in contamination cleanups to develop innovative technologies that are more cost effective, efficient, and expedient.

Packer Isolation System with Sonic Drill

WATER SAMPLING

PACKER ISOLATION METHOD

The packer isolation groundwater sampling system is designed for collection of groundwater samples in dense overburden or bedrock boreholes where the Push-Ahead method may be less effective.

THE PROCESS

1. A sonic drill (typically with a four inch core barrel with six inch override casing) proceeds to the base of the interval from which a groundwater sample is to be collected.
2. Once that interval is achieved, the sonic core barrel is removed from the casing, and a stainless steel screen and packer assembly is inserted to the base of the sonic casing.
3. The sonic casing is then extracted to expose the screened interval to the formation and the packer is inflated inside of the sonic casing to isolate the screen.
4. Purging of the temporary well proceeds until stabilization parameters are met. Groundwater samples are then collected.

BENEFITS

1. Screen lengths may be adjusted to match specific intervals to be sampled.
2. Samples may be collected within any formation through which a sonic rig can drill.
3. Four inch diameter screens may be used which allows for higher purge rates and greater sample depths using larger submersible pumps.

Cost comparison of multilevel monitoring technologies (Malcolm Pirnie 2011)

Assumptions

- DTW 10'
- Today depth of wells 150'
- Number monitoring points: 3
- Geology: bedrock
- Borehole size: 6"
- Purpose: Groundwater sampling and water level measurements
- Channels for CMT: 7
- Installation method: sand and bentonite (i.e., no packers)

Table 3-1. Initial Capital Cost Comparisons for ZIST™ and Multi-Level Monitoring Systems

System	Major Components	Estimated Costs
ZIST™ (BESST, Inc.)	Blatyni pumps; teflon tubing; riser pipe; well screens; bentonite pellets	\$7,500 (not including transducers)
	ZIST™ transducer housings; Troll 500 transducers; Troll cables; programming cable	\$17,400 (including transducers)
	ZIST™ training for installation and operation (2 days)	\$3,500 (includes travel and expenses)
CMT (Solinst, Inc.)	CMT-7-Channel tubing; centralizers; wellhead; installation tool kit	\$1,800
	Solinst training for installation and operation (2 days)	\$3,600 (includes travel and expenses)
Westbay (Schlumberger)	Plastic MP38 casing	\$6,400 (casing components)
		\$1,600 (2-day rental of sampling equipment)
		\$33,000 (purchase of sampling equipment)
FLUTE	Westbay technical services – for training in equipment operation	\$4,000 (includes travel and expenses)
	150 ft Water FLUTE with 3 ports	\$10,400 (FLUTE only)
	Ancillary equipment for installation – pump tube; wellhead roller rental; winch plate rental; pump plate rental; shipping reels	\$2,900 (for ancillary installation equipment)
	FLUTE labor to install system	\$6,000 (including travel and expenses)

Materials cost:

Bias in groundwater samples caused by wellbore flow

TE Reilly, OL Franke, GD Bennett

Journal of Hydraulic Engineering, 1989 - ascelibrary.org

1989

Design of physical installations and sampling procedures for ground-water monitoring networks, particularly for detection and analysis of possible contaminants, is a topic of great scientific and practical interest at the present time. Recent practice in the design of monitoring networks associated with known contaminant sources sometimes includes an array of monitoring wells with long well screens (up to 50 feet or more). Numerical experiments with a detailed three-dimensional ground-water flow model indicate that significant wellbore flow can occur in contaminant monitoring wells with long well screens that are embedded in homogeneous aquifers with very small vertical head differences in the aquifer. This "short circuiting" of flow through boreholes should exist at some level on all scales. Consideration of the general flow pattern within the borehole, the flow pattern in the aquifer adjacent to the borehole, and the process of obtaining water samples from the borehole suggests that in many situations the practice of installing long well screens in contaminant monitoring wells should be abandoned.
